INDEX

NAME INDEX

- Abelson (P.), [S. F. Cook, K. G. Scott and], Deposition of Radio-phosphorus in Tissues of Growing Chickens, 944
- Abercrombie (M.), elected a junior research fellow in zoology at Queen's College, Oxford University, 38
- Abraham (R. P.), elected to a readership in chemistry at Queen's College, Oxford University, 38; and Prof. R. Robinson, Crystallization of Lysozyme, 24
- Abraham (W. E. V.), Geological Aspects of Deep Drilling Problems, 73
- Adam (Miss M. G.), appointed assistant tutor in science at St. Hugh's College, Oxford, 38
- Adam (Flight-Lieut. M. J.), World's Air Altitude Record, 56
- Adam (Prof. N. K.), Pollution of Sea and Shore by Oil, 100; Use of the Word Substrate, 158
- Adams (Dr. F. D.), awarded the Flavelle medal of the Royal Society of Canada, 287
- Adams (Dr. R.), Inter-racial Marriages in Hawaii (*Review*), 665
- Aebersold (P. C.), [G. N. Snell and], Production of Sterility in Male Mice by Irradiation with Neutrons, 779
- Agar (Prof. W. E.), Cytology of *Lepidosiren*, 931
- Ahier (G.), Christiansen Filters, 477
- Ainsworth (Dr. G. C.), The Plant Diseases of Great Britain: a Bibliography (*Review*), 91
- Airey (Dr. J. R.), [death], 536; [obituary article], 706
- Aitken (A. C.), Studies in Practical Mathematics (2), 124
- Aitken, Allott, Castleden and Walker, Potassium and Paralysis, 267
- Aldersloff (Prof. H.), [death], 455
- Alexander (W.), and J. Swaffield, Magnetostriction, 1068
- Algar (J.), and Isabella P. Carey, Synthesis of Flavonols: Oxidation of Flavindogenides, 292
- Alington (Very Rev. Dr. C. A.), elected president of the University of Durham Philosophical Society, 967
- Allen (Dr. C.), Modern Discoveries in Medical Psychology (*Review*), 343
- Allen (Dr. J. F.), Dr. B. Pefarls and M. Zaki Uddin, Heat Conduction in Liquid Helium, 62
- Allibone (Dr. T. E.), and J. M. Meek, Development of the Spark Discharge, 804
- Allmand (Prof. A. J.), appointed Daniell professor of chemistry at King's College, London, 942
- Almquist (H. J.), Crystals with Vitamin K Potency, 25
- Alty (T.), Sublimation and Condensation of Crystals, 814
- Amat (M.), [J. Duclaux and], Ultra-filters of Carborundum, 656
- Anderson (Dr. G. C.), conferment upon, of an honorary doctorate by Queen's University, Belfast, 166
- Anderson (Dr. J.), appointed representative of the Scottish Beekeepers' Association on the Bee Research Committee, 274
- Anderson (Dr. J. S.), Structure of Organic Molecular Compounds, 583; Constitution of the Poly-acids, 850
- Andersen (F. G.), Citrus Mannring, 976
- Andrade (Prof. E. N. de C.), The Mechanism of Nature, being a simple approach to Modern Views on the Structure of Matter and Radiation. Revised edition (*Review*), 280; Lord Rutherford, 753; Interpretations of Atomic Constitution, 894; and R. C. Parker, Absolute Measurements of Sound Intensity, 34
- Angell (J. R.), and others, A History of Psychology in Autobiography. Vol. 3. Edited by C. Murchison (*Review*), 830
- Angstrom (A.), A Coefficient of Humidity of General Applicability, 160
- Angus (Prof. R. W.), elected an honorary member of the Engineering Institute of Canada, 274
- Anthony (Dr. H.), 'Shiva's Temple', Arizona, 613
- Arakatsu (B.), K. Kimura and Y. Uemura, Expulsion of Neutrons from Lead by Cosmic Rays, 277
- Arbour-Stephens (Dr. G.), Clean Milk and Pasteurisation, 614
- Arensberg (Dr. C. M.), The Irish Countryman: An Anthropological Study (*Review*), 299
- Armstrong (A. L.), Rev. N. Jones and H. B. Maufe, Antiquity of Man in Rhodesia, 469
- Armstrong (Dr. E. F.), Tendencies of World Power Development, 706; awarded an honorary association of the Birmingham Central Technical College, 929
- Armstrong (Prof. H. E.), [death], 97; [obituary article], 140; (late Prof. H. E.), Ammonolysis: the Life Element, 134
- Armstrong (J. M.), Cytology of the genus *Poa*, 368
- Arthur (J. C.), and G. B. Cummins, Rust Fungi of the Philippines, 648
- Ashby (Dr. E.), appointed professor of botany in Sydney University; work of, 883; resignation from Bristol University, 904
- Asmus (Dr. R.), Organische Synthesen (Organic Syntheses) (*Review*), 486
- Asbury (Dr. W. T.), Relation between 'Fibrous' and 'Globular' Proteins, 968; X-Rays and Wool Fibre, 1069
- Aste-Salazar (J. H.), [J. W. Thompson, W. Corwin and], Physiological Patterns and Mental Disturbances, 1062
- Aston (Dr. F. W.), Packing Fractions of Krypton and Xenon, 149; A Second-order Focusing Mass Spectrograph and Isotopic Weights by the Doublet Method, 905
- Atanasiu (M.), Natural Convection in Liquids, 985
- Atkinson (Dr. R. d'E.), appointed chief assistant at the Royal Observatory, Greenwich; work of, 457
- Attems (Dr. C.), Millipedes of India, 72
- Audubert (R.), Ultra-violet Emission Spectrum of the Slow Thermal Dissociation of Silver Nitride, 518
- Auerbach (Dr. C.), [Prof. F. A. E. Crew and], 'Spheroidal': A Mutant in *Drosophila funebris* affecting Egg Size and Shape, and Fecundity, 124; New Mutation in *Drosophila*, 898
- Aufrère (L.), Boucher de Perthes and the Foundations of Prehistoric Archaeology, 261
- Auger (P.), P. Ehrenfest, jun., A. Freon and Mme. Thérèse Grivet, Mechanism of the Production of Cosmic Bundles, 292
- Auger (V.), and Mile. Nina Ivanoff, Molybdenum Blues, 293
- Augustus, Emperor, Bicentenary of the, 577
- Austin (Lord), conferment upon, of an honorary doctorate by Birmingham University, 80
- Aveling (Prof. F.), Science in Psychology (*Review*), 909
- Ayres (Prof. Q. Q.), Soil Erosion and its Control (*Review*), 445
- d'Asambuja (L.), International Co-operation for the Continuous Observation of the Sun, and its First Results, 208

- Ba Thi (M.), T. G. Hunter and A. W. Nash and others, Solvent Dewaxing, 1105
- Baber (T. D. H.), appointed an assistant lecturer in mathematics in Sheffield University, 735
- Bacharach (A. L.), Adsorption Columns (*Review*), 48; Harris's Vitamins in Theory and Practice (*Review*), 302; and H. E. Glynne, Liver Extract and Haemoglobin in Rats, 896; [Dr. B. P. Wiener and], Effect upon Sex Behaviour of a Diet Deficient in Vitamin E, 972
- Bachelery (A.), Electrification of the Paris-Orléans and Midi Railways, 1025
- Bacich (Dr. P.), appointed lecturer in embryology in Glasgow University, 654
- Baddar (F. G.), and F. L. Warren, Synthesis of Benzanthrones, 321
- Badenhuizen, jun. (N. P.), [Prof. K. H. Meyer and], Transformation of Hydrate Cellulose into Native Cellulose, 281
- Baden-Powell (Major B. F. S.), [death], 611
- Baehni (C.), Male Inflorescence of *Scyphostegia borneensis*, 737
- Beckland (Prof. L. H.), conferment upon, of an honorary doctorate by Edinburgh University, 80
- Beens (L.), and F. M. Yenks, Effect of Moulds upon Tanning Liquors, 637
- Baerts (F.), and R. Vandewijer, Alkalinity of the Ash and Loss of Chlorine on Incineration, 943
- Bailey (C. R.), Infra-red Absorption of Carbon Disulphide, 861
- Bailey (Prof. E. B.), Prof. A. Heim, 573
- Bailey (Prof. K. O.), The Retardation of Chemical Reactions (*Review*), 340; Behaviour of Cylinders of Inflammable Gas in a Fire: Extinguishing Flames by Coal Gas, 503; Tritium or Triterium?, 590; and G. T. Taylor, Retardation of Chemical Reactions, 327
- Baily (Prof. F. G.), and others, Universities and Education, 689
- Bake (Dr. A. A.), appointed a senior research fellow of Brasenose College, Oxford, 694
- Baker (Dr. J. R.), Nomenclature of the Seasons, 890
- Balavoine (P.), Variation of the Iodine Value of Drying Oils according to their Origin, 125
- Balchin (W. G. V.), Erosion Surfaces of Cornwall, 326
- Bald (J. G.), Ecology of Tomato 'Spotted Wilt' Virus, 1019; and G. E. Briggs, Aggregation of Virus Particles, 111
- Baldick (K. J.), and F. Luoma, Derivatives of 6:7-Dimethoxybenzoparathiazine, 695
- Baltazard (M.), [G. Bianco and], Cross Immunity between the Pustular Fever and Purpura Fever of the Rocky Mountains, 905
- Baly (Prof. E. O. C.), Photosynthesis of Carbohydrates *in vitro*, 930
- Bamford (O. H.), elected a fellow of Trinity College, Cambridge, 735; [Prof. R. G. W. Norrish and], Photodecomposition of Aldehydes and Ketones, 195
- Bangham (Prof. D. H.), S. Mosallam and Z. Sawaris, Visible Adsorbed Films and the Spreading of Liquid Drops at Interfaces, 237
- Barfis (E.), Intoxicants in Sarawak, 936
- Banting (Sir Frederick), Early Work on Insulin, 901
- Barber (A.), [Dr. F. O. Champion and], Production of Positron and Electron Pairs by bombardment of Mercury with β -Particles of Low Energy, 105
- Barday (A.), Chemistry: A Brief Outline of its History and Development, 232
- Barger (Prof. G.), appointed regius professor of chemistry in Glasgow University, 537, 556; work of, 537
- Barkworth (Capt. H.), and L. W. L. Cole, Acids and Off-Flavoured Milk, 324
- Barling (Sir Harry Gilbert), conferment upon, of an honorary doctorate by Birmingham University, 80
- Barnes (Dr. O.), Masses and Parallaxes of Binary Stars, 286
- Baron (J.), and P. Laffitte, Inflammation of Acetaldehyde, 477
- Barrer (R. M.), Nature of the Diffusion Process in Rubber, 106
- Barrett (Sir James), Central (Native) Medical School, Suva, Fiji, 472
- Barrett (Sir William), Personality Survives Death: Messages from. Edited by his wife (*Review*), 1078
- Barrie (H. J.), appointed demonstrator in pathology in Sheffield University, 904
- Barrie (Miss M. M. O.), Vitamin E Deficiency in the Suckling Rat, 426
- Barry (A. M.), appointed a Frank Edward Elmore student in Cambridge University, 123; awarded the E. G. Fearnside scholarship of Cambridge University, 291
- Barry (D. R.), Changes of Colour by Injection of Pituitary Extracts in a Dogfish (*Scyllorhynchus canicula*), 769
- Bartlett (Prof. F. O.), Native Science in Southern Sudan (*Review*), 338
- Bartley (Mary A.), [W. J. Robbins, A. G. Hogan, L. R. Richardson and], Pyrimidine and Thiazole Intermediates as substitutes for Vitamin B, 779; [W. J. Robbins and], Thiazole and the Growth of Excised Tomato Roots, 779
- Barton (H. J.), [H. W. Newton and], Bright Solar Eruptions and Radio Fading in 1935-36, 688
- von Basch (Samuel Siegfried Karl) (1837-1905); work of, 393
- Bassière (M.), Structure of Cadmium Nitride (Hydrazoate), 125
- Bate (Dorothea M. A.), [Elinor W. Gardner and], The Bone-bearing Beds of Bethlehem: Their Fauna and Industry, 431
- Bateman (Dr. J. B.), International Congress for Short Waves in Physics, Biology and Medicine, Vienna, 372; Mitogenetic Radiation and the Theory of Nerve Excitation (*Review*), 565; Dr. H. Loewenthal and Dr. H. Rosenberg, Alleged Specific Effects of High Frequency Fields on Biological Substances, 1063
- Bates (R. G.), and W. C. Vosburgh, Potential of the Iodine Electrode, 776
- Batten (Miss Jean), awarded the gold medal of the Royal Aero Club, 844
- Bauer (D. J.), elected Michael Foster student in physiology in Cambridge University, 291
- Bauer (P. T.), awarded the Wrenbury scholarship of Cambridge University, 291
- Bauer (S. H.), Structure of Diborane, 552
- Bawden (F. O.), and N. W. Pirie, Crystalline Preparations of Viruses, 1018
- Bax (L. M.), renewal to, of a Salters' Institute fellowship, 274
- Baxter (A. M.), awarded the Sir William White post-graduate scholarship of the Institution of Naval Architects, 422
- Bayley (D. S.), and H. R. Crane, The β -rays from Lithium and Boron Isotopes, 76
- Beadle (G. W.), and B. Ephrussi, Ovary Transplants in *Drosophila melanogaster*; Meiosis and Crossing-over in Super Females, 779
- Beadle (L. C.), and F. A. Booth, An Inexpensive Low-Temperature Thermo-stat, 279
- Beadnell (Surgeon Rear-Admiral C. M.), An Inquiry into "Marvels" (*Review*), 87
- Beal (J. M.), Bud Development in *Lilium Harrisii* following Treatment with Indoleacetic Acid, 519
- Beams (Prof. J. W.), [Dr. F. T. Holmes and], Frictional Torque of an Axial Magnetic Suspension, 30
- Beatty (A. Chester), gift to London University for a scholarship in radiology, 778; gift to the Royal Cancer Hospital, 844
- Beaumont (A.), [death], 309; and P. H. Gregory, A Leaf-spot Disease of *Gerbera Jamesoni*, 511
- Bedson (Prof. S. P.), conferment upon, of an honorary doctorate by Queen's University, Belfast, 166
- Běhounek (Dr. F.), and F. V. Novák, Retention of Radioactive Substances in the body of Rats and the Lethal Dose, 106
- Behrens (Hon. Mrs.), endowment of a Olive Behrens lectureship in Leeds University, 166
- Beischer (D.), and A. Winkel, Size of Particles Responsible for Ferromagnetism, 202
- Belcher (D.), Effect of Viscosity on Ionic Mobilities, 810

- de Belin (G. A.), appointed assistant lecturer and research assistant in the department of metallurgy of Sheffield University, 207
- Bell (Prof. E. T.), *Man of Mathematics (Review)*, 525
- Ball (Miss Florence O.), appointed research assistant in textile physics in Leeds University, 942
- Bellingham (L.), A Double Refraction Effect in Certain Fatty Materials, 70
- Beltrán (Prof. J. R.), appointed professor of the history of medicine at Buenos Aires University, 641
- Bolz (M. H.), [J. H. Michell and], *The Elements of Mathematical Analysis*, 2 Vols. (*Review*), 681
- Benjamin (Dr. M.), and R. O. Jenkins, Surface migration of Barium, 152
- Benndorf (H.), and M. Mitleacher, Stationary Air Currents in Closed Vessels, 1112
- Bennett (Miss A.), Plant Ecology of Limestone Pavements, 781
- Benson (Dr. E.), Grammar Schools and Technical Education, 79
- Bentath (A.), and Prof. A. Szent-Györgyi, Vitamin P, 426
- Berg (Dr. W. F.), Mechanism of the Photographic Process, 997
- Bergel (Dr. F.), [Dr. A. R. Todd, H. Waldmann, T. S. Work and], Constituents of Vitamin E Concentrates from Rice- and Wheat-Germ Oils, 861
- Bergey (Prof. D. H.), [death], 576
- Bernal (J. D.), appointed professor of physics at Birkbeck College, 904
- Bernard (R.), Spectrum of Nitrogen and Atmospheric Pressure at High Altitudes, 930
- Bernstein (R. E.), Excretion of Vitamin C in Sweat, 684
- Berthelsen (H.), [A. Hjärre and], Method for Fixing Neutral-Red in Supra-Vital Stained Blood Smears, 155
- Bertrand (G.), Presence and Distribution of Boron in the Potash Salts of Algae, 820
- Bertrand (P.), Comparative Ontogeny of Living and Fossil Phanerogams, 1111
- Best (R. J.), Artificially Prepared Visible Paracrystalline Fibres of Tobacco Mosaic Virus Nucleoprotein, 547
- Bevin (H.), Trades Union Congress and Science, 457
- Bewley (Dr. W. F.), Science in Relation to the Glasshouse Industry, 387
- Beyling (Dr. O.), awarded the medal of the Institution of Mining Engineers, 967
- Bhabha (Dr. H. J.), awarded an 1851 exhibition studentship, 38
- Bhagavantam (Prof. S.), and B. Sundara Rama Rao, Adiabatic and Isothermal Compressibilities of Heavy Water, 1099
- Bhatnagar (Prof. S. S.), Dr. H. Lersheim and Mohan Lal Khanna, The Ground State of the Se₂ Molecule, 152
- Bialynski-Birula (Dr. A. A.), [death], 97
- Bialing (Prof. R.) and others, Die europäischen und mediterranen Ottern und ihre Gifte: Grundlagen zur Darstellung eines wirksamen Schlangenserums (*Review*), 744
- Bilger (G.), Potential of Polygons and Elementary Geometry, 376
- Bilham (E. G.), Effects of Obstacles on Sunshine Records, 648; Weather and Water Supplies, 964
- Biquard (Dr. P.), The Palace of Discovery at the Paris International Exhibition, 1937, 328
- Birch (A. J.), Detection and Estimation of α -Phellandrene in Essential Oils, 377
- Birch (Prof. de Burgh), [death], 536; [obituary article], 715
- Biswas (K. P.), Aquatic and Marsh Plants of India and Burma, 592
- Bixette (H.), and B. Tsai, Magnetic Rotatory Power of Compressed and of Liquefied Nitric Oxide, NO, 208
- Black (M.), appointed a demonstrator in geology in Cambridge University, 123
- Black (Prof. N. H.), New Laboratory Experiments in Practical Chemistry (*Review*), 173; and J. B. Conant, New Practical Chemistry: Fundamental Principles Applied to Modern Life (*Review*), 178
- Blackett (Prof. P. M. S.), appointed Langworthy professor of physics in Manchester University, 207; work of, 962
- Blackman (Dr. F. F.), presentation of a portrait of, to the Botany School, Cambridge, 845
- Blackman (Prof. V. H.), conferment upon, of the title of emeritus professor by London University, 778
- Blackton (Dr. S. C.), Spontaneous Electrical Charge of Fine Coal Dust, 280; Electrotor Smoke and Dust Meter, 331, 582; New Inventions Exhibition, 982; awarded the Founder's silver medal and the Institute of Patentees' silver medal, 1058
- Blackwell (Miss Elizabeth), Germination of Resistant Spores of *Blastocladiella Pringsheimii*, 933
- Blair (Dr. G. W. Scott), appointed head of the chemistry department of the National Institute for Research in Dairying, 61; 654
- Blanc (G.), and M. Baltazard, Crossed Immunity between the Pustular Fever and Purpura Fever of the Rocky Mountains, 905
- Blatter (late Rev. E.), and W. S. Millard, Some Beautiful Indian Trees (*Review*), 633
- Blau (Dr. Marietta), and Dr. Hertha Wambacher, Measurement of the Length of Proton Tracks by the Photographic Method, 252; awarded the Ignaz L. Lieben prize of the Vienna Academy of Sciences, 332; Disintegration Processes by Cosmic Rays with the Simultaneous Emission of Several Heavy Particles, 585
- Bless (A. A.), Effects of the Length of X-Ray Waves on Seeds, 83
- Blodgett (K. B.), and L. Langmuir, Built-up Molecular Films, 470
- Bodson (H.), [J. Timmermans and], Surface Tension of Water and that of Heavy Water, 293
- Bogert (Prof. L. J.), Dietetics Simplified: the Use of Foods in Health and Disease. With Laboratory Section by M. T. Porter (*Review*), 829
- Bohnecke (G.), Temperatur, Salzgehalt und Dichte an der Oberfläche des atlantischen Ozeans. Lief. 1; Atlas (*Review*), 704
- Bohr (Prof. Niels), Lord Rutherford, 752; 1048
- Bois (Prof. D.), Les plantes alimentaires chez tous les peuples et à travers les âges: histoire, utilisation, culture. Vol. 4. (*Review*), 787
- Bolland (J. L.), and Dr. H. W. Melville, Analysis of Ternary Gas Mixtures by Thermal Conductivity Measurements, 63
- Bolliger (A.), Compounds of Creatinine with Alkaline Hydroxides, 377; Red Compounds formed by Picric Acid and Creatinine in the Presence of Sodium Hydroxide, 519
- Bomke (Dr. H.), Vakuumspektroskopie (*Review*), 528
- Bond (O. J.), Biology and the New Physics: a Plea for a consistent Philosophy of Life (*Review*), 953
- Bond (Dr. G.), Excretion of Nitrogen by Leguminous Plants, 683
- Bond (Dr. W. N.), [obituary article], 716
- Bonét-Maury (P.), Utilization of Photo-Elements with Semi-Conducting Layer for Radioactive Measurements, 208; Optical Properties of Bacterial Suspensions, 985
- Bonhoeffer and Fredenhagen, Cannizzaro Reaction, 369
- Booth (F. A.), [L. C. Beadle and], An Inexpensive Low-Temperature Thermostat, 279
- Bordet (Prof. J.), awarded the Grand Cross of the Order of Leopold, 104
- Borocco (A.), [L. Hackspill and], Compounds of the Isotope 2 of Hydrogen with the Alkali Metals (Alkaline Deuterides), 82
- Bosch (Prof. O.), elected president of the Kaiser Wilhelm Society for the Advancement of Science, 274
- Bose (Prof. D. M.), Absorption Spectra Evidence of the Decomposition of the Ground Term of Nd⁺⁺ Ion due to Crystalline Fields, 109
- Bose (Sir Jagadis Chandra), [death], 932; [obituary article], 1041

- Bose (Dr. S. R.), Polyporaceous Fungi, 592; and S. N. Sarkar, Enzymes of Wood-Rotting Polypores, 813
- Boesler (J.), and H. Roure, Disappearance of Biela's Comet, 40
- Botha (Lt.-Col. C. G.), Science of Archives in South Africa, 374
- Bouchard (Charles), (1837-1915), work of, 457
- Bouckaert (Prof. J. J.), awarded the Gluge prize of physiology of the Belgian Royal Academy of Sciences, 274
- Boulenger (Dr. G. A.), [death], 960
- Bourdoull (Mme. O. Sosa), Composition of the Pollen of Some Ranunculaceae and on their Systematic Position, 656
- Boutry (G. A.), and G. Tréherne, Commutable and Stable Electrical Contacts, 251
- Bowen (E. G.), [R. A. Watson-Watt, A. F. Wilkins and], Reflection of Radio Waves in the Atmosphere, 512
- Bowen (Prof. I. S.), Prof. R. A. Millikan and Dr. H. V. Neher, Measurement of the Nuclear Absorption of Electrons by the Atmosphere up to about 10^{10} Electron-Volts, 23
- Bowen (Prof. N. L.), elected a foreign correspondent of the Geological Society of London, 883; work of, 884
- Bowman (J.), awarded a Royal Asiatic Society's Universities Essay prize, 967
- Boyd (J. D.), appointed lecturer in anatomy in Cambridge University, 123
- Boyes (J. W.), and W. P. Thompson, Endosperm and Embryo in Reciprocal Cereal Crosses, 511
- Boys (Sir Charles Vernon), Weeds, Weeds, Weeds (Review), 994
- Bradley (A. J.), H. J. Goldschmidt, H. Lipson and A. Taylor, Investigation of Equilibrium Diagrams of Ternary Alloys by X-Rays, 543; and A. Taylor, An X-Ray Investigation of the cause of High Coercivity in Iron-Nickel-Aluminium Alloys, 1012; and H. Lipson, Rapid Survey of Ternary Alloy Systems by X-Rays, 1069
- Bradley (Dr. O. C.), [death], 1043
- Bragg (Sir William), elected an honorary associate of the Royal Institute of British Architects, 21; conferment upon, of an honorary doctorate by Edinburgh University, 80; Lord Rutherford, 752; recommended for re-election as president of the Royal Society, 840; appointed a member of the advisory council to the Committee of the Privy Council for Scientific and Industrial Research, 888; The Grain-Like Structure of Solids, 954; The Pilgrim Trust Lecture, 961
- Bragg (Prof. W. L.), Atomic Structure of Minerals (George Fisher Baker lecture) (Review), 783
- Braun (A.), Dr. P. Prelszwerk and P. Scharrer, Detection of α -Particles in the Disintegration of Thorium, 682
- Braunstein (Prof. A. E.), Specificity of the Salicylic Aldehyde Reaction of Conka-Straub, 427; and M. G. Kritsmann, Formation and Breakdown of Amino Acids by Intermolecular Transfer of the Amino Group, 503
- Breen (J.), J. Keane and T. J. Nolan, Chemical Constituents of Lichens found in Ireland—*Pertusaria concolorata*, 333
- Brenchley (Dr. Winifred E.), Pasture Problems, 918
- Brewster (A. B.), [obituary article], 881
- Brickwedde (F. G.), [R. B. Scott and], Liquid Parahydrogen, 1020
- Bridgman (Prof. P. W.), Polymorphic Transitions of Inorganic Compounds to 50,000 kgm./cm.², 83; Polymorphism under Pressure, 899
- Briegleb (Dr. G.), and W. Leuppe, Raman Spectra of Oxonium Compounds, 236
- Briggs (G. E.), [J. G. Bald and], Aggregation of Virus Particles, 111
- Briggs (L. J.), Standardization of Physical Units, 122
- Bright (Sir Charles), [death], 1002
- Brightman (R.), Reflections on Life (Review), 341; Social Theory and Discipline (Review), 481
- Brindley (Dr. G. W.), and P. Ridley, Asymmetry in Metals of Hexagonal Structure, 461
- Briner (E.), [D. Monnier, B. Sum and], Raman Spectra of Acrylic Acid and of Methyl Methacrylate, both Monomer and Polymerized, 737; and E. Perrottet, Complementary Results on the Catalytic Action of Ozone in the Oxidation of Aldehydes, 737
- Briscoe (Prof. H. V. A.), Dust Control in Industry, 773; Intermediate Chemistry (Review), 910
- Brocket (Lord), gift of Devil's Dyke, Wheathampstead, as an open space, 764
- Brockway (L. O.), [L. Pauling and], Carbon-Carbon Bond Distances, 688
- de Broglie (Duc), Lord Rutherford, 1050
- Brohult (S.), Splitting of the Haemocyanin Molecule by Ultra-Sonic Waves, 805
- Broniewski (W.), S. Przedpełski and S. Sulowski, Some Physical and Chemical Properties of Very Pure Steels, 334
- Brooke (G. B.), and A. G. Waddington, Determination of Alumina in Metallic Aluminium, 858
- Brooks (C. F.), and A. H. Tiessen, Meteorology of Great Floods in the Eastern United States, 511
- Broom (Dr. R.), Discovery of a Lower Molar of *Australopithecus*, 681
- Brown (A. B.), and R. G. H. Cormack, Heterocauxin and Cambial Activity, 898
- Brown (A. G.), [M. B. Crane and], Incompatibility and Sterility in Sweet Cherries, 1019
- Brown (Dr. D.), Sound-Films as Diffraction Gratings for Visual Fourier Analysis of Sound-Waves, 1099
- Brown (J. M.), appointed lecturer in political science in the United College, St. Andrews University, 207
- Brown (L. W.), [Dr. F. W. G. White and], Annual Variation of the Absorption of Wireless Waves in the Ionosphere, 931
- Brown (Prof. P. E.), [death], 226
- Brown (R. S.), Anatomy of *Ophelia cluthensis* McGuire, 292
- Browne (E. T.), [death], 1043
- Bruce (E. L.), Gold Deposits of the Canadian Shield, 116
- Bruce (M. M.), Utilization of Leisure, 229
- Bruck (Dr. H.), appointed first junior observer in the Cambridge Solar Physics Observatory, 819
- Brunner (Dr. O.), awarded the Rudolf Wegscheider prize of the Vienna Academy of Sciences, 332
- Brunovsky (B. K.), [Prof. W. I. Vernadsky, O. G. Kunaheva and], Concentration of Mesothorium-I by Duckweed (*Lemna*), 317
- Brunt (Prof. D.), and others, Investigation of the Upper Air, 876
- de Bruyne (Dr. N. A.), awarded the Summe gold medal of the Royal Aeronautical Society, 1094
- Budden (K. G.), and J. A. Ratcliffe, An Effect of Catastrophic Ionospheric Disturbances on Low-frequency Radio Waves, 1060
- Buffle (J. P.), Origin of the Calcium Bicarbonate in the Waters of the River Versoix (Canton of Geneva), 125

TITLE INDEX

- α -Amino-Acids, Naturally Occurring, Absolute Configuration of the, R. C. Rainey, 160
- α -Phellandrene in Essential Oils, Detection and estimation of, A. J. Birch, 377
- α -Phellandrene, derivative of, Conversion of β -Phellandrene into α , Dr. N. F. Goodway and T. F. West, 934
- Aberdeen University, conferment of an honorary doctorate on Prof. T. Shennan, 123
- Abyssinia, Naturalists in, [1837], 1072
- A.C. Measurements, Commercial, G. W. Stubbings. Second edition (*Review*), 91
- Academic Assistance Council, Third Report of the, 169
- Acetaldehyde, Inflammation of, J. Baron and P. Laffitte, 477
- Acetanilides, 2: 6-Disubstituted, Evidence of restricted rotation about the N—C Bond in, Dr. L. Hunter and H. O. Chaplin, 896
- Achanarras, Middle Devonian Fish Fauna of, C. Forster Cooper, 292
- Acidosis and Off-flavoured Milk, Capt. H. Barkworth and L. W. L. Cole, 324
- Acrostas* Linn., New Forms of the Genus, J. Hewitt, 1028
- Acoustical Conference, First International, 870
- Actinium, Optical Spectrum of, Mlle. Willy A. Lub, 40
- Adrenalin, Changes in the Hyperglycaemic Action of, by the addition of Zinc Salts, H. Schwab, 943
- Adsorption Columns, A. L. Bacharach (*Review*), 48
- Aerial Protection in Belgium, 1008
- Aerodynamic and Electrodynamio Equations, N. P. Kosterin, 244
- Aerodynamics: A Text-book of (*Review*), 175; Practical, Elements of, Prof. B. Jones (*Review*), 175; Dr. N. A. V. Piercy (*Review*), 635
- Aero Engine, Metallurgy and the, Dr. D. R. Pye, 516
- Aeronautical Research Committee, Report for 1935-36, 289
- Aeroplanes Fly, Why, A. Elton and R. Fairthorne (*Review*), 1035
- Affinity, Thermodynamic Theory of, Prof. T. De Donder and Prof. P. Van Rymelberghe (*Review*), 344
- Afforestation in the Lake District: a reply to the Forestry Commission's White Paper of 26th August, 1936, H. H. Symonds (*Review*), 214
- Africa: East, Higher Education in, 781; (*Review*), 951; Central, Blood Groups in, R. Eledon Dew, 927
- African: Pleistocene Mammals (*Review*), 6; Agricultural Problems, Dr. B. A. Keen (*Review*), 698; Natives, Higher Education for, 781
- Aftermath: a Supplement to the Golden Bough, Sir James George Fraser (*Review*), 260
- Agricultural: Products as Raw Materials for Industry, Sir Harold Hartley (Mather lecture), 221; Research Council, awards made to P. J. Faulks, R. S. Russell, F. H. Malpass, J. Wilson, G. H. L. Dickier, J. W. Whittick, F. D. Asplin and Miss K. M. Massey, 274; Research in Great Britain, 421; Marketing Policy, A. N. Duckham, 887
- Agriculture: Seventeenth International Congress of, at The Hague, 85; British, The Rehabilitation of, 78; State Intervention in, J. M. Oaie, 416; State Intervention and, 601; Boron in, Miss Katherine Warington, 1016
- Ainou, La civilisation et les cultures arctiques, Prof. G. Montandon (*Review*), 386
- Air: Altitude Record, World's, Flight-Lieut. M. J. Adam, 56; -Conditioning Unit, An, 101; Record, Long Distance, Col. M. Gromoff, 143; -Conditioning, Future of, 579; Navigation: British Empire edition, Lt.-Comdr. P. V. H. Weems. Edited by A. J. Hughes and P. F. Kveritt (*Review*), 630; Defence and the Civil Population, Dr. H. M. Hyde and G. R. F. Nuttall (*Review*), 661; Raid Precautions. (*Review*), 661; Memorandum No. 5, 967; Sir Samuel Hoare, 1044; Ionization of, at Low Pressures by γ -Rays, H. Macho and O. Markowicz, 1074; Currents, Stationary, in Closed Vessels, H. Banndorf and M. Mittlecher, 1112
- Aldehydes and Ketones, Photo-decomposition of, Prof. R. G. W. Norrish and C. H. Bamford, 195
- Alexander's Electric Telegraph, [1837], 984
- Algebra, College, Lectures on, S. B. Dandekar (*Review*), 831
- Alibert, Baron [1837], 777
- Alkaline-Earth Carbonates, Polymorphic Changes of the, K. E. Zimens, 203
- Alkyl: Ethers, Nitric Oxide and, Prof. M. W. Travers, 107; Halides, Ionic Dissociation of the, A. Tian and E. Gand, 293; Series Effect on the Dipole Moments of Some, E. G. Cowley and Prof. J. R. Partington, 1100
- All-India Oriental Conference, Ninth, Prof. F. W. Thomas elected president of the, 55
- Alloys: of Iron and Palladium, Identification of various phases by Magnetic Study and by the X-Rays in, R. Hooart and M. Fallot, 81; of Iron and Iridium, Magnetic properties of, M. Fallot, 820; Deformation of the Macrostructure of some Two-phase, by Cold-rolling, H. Unkel, 857; Metals and, Studies of, 857; of Silver, Tin and Mercury, Constitution of the, Dr. Marie L. V. Gayler, 858; of Iron and Rhodium, Magnetic Properties of, M. Fallot, 905; Iron-Nickel-Aluminium, High Coercivity in, An X-Ray Investigation of the Cause of, Dr. A. J. Bradley and A. Taylor, 1012
- Alternating Current Measurements at Audio and Radio Frequencies, Dr. D. Owen (*Review*), 637
- Aluminium: Nuclear Moments of, D. A. Jackson and Dr. H. Kuhn, 110; Manufacture in Great Britain, W. M. Morrison, 163; and its Light Alloys, The Technology of, Prof. A. von Zeierleder. Translated by A. J. Field (*Review*), 176
- Amariyllidaceae, Classification of the, J. R. Sealy, 73
- Amariyllids, Culture of, 861
- Ambis*, No. 1, 188
- American: Documentation Institute, 273; Men of Science, Famous, J. G. Crowther (*Review*), 439; Museum of Natural History, Catalogue of Meteorites in the, Dr. C. A. Reeds, 542; Philosophical Society, Library of the, 615; Chemical Society, award of the Francis B. Gervan gold medal to Dr. Emma R. Carr; presentation of the society's one thousand dollar award to Dr. E. B. Wilson, jun., 888; Earthquakes, Recent, 899; Academy of Arts and Sciences, Research Grants of the, 1106
- Amino-Acids: α , naturally occurring, Absolute Configuration of the, R. C. Rainey, 160; Formation and Breakdown of, by Intermolecular Transfer of the Amino Group, Prof. A. E. Braunschtein and M. G. Kitzmann, 503
- Amines, Action of Nitrous Acid on, J. O. Earl and N. G. Hills, 1105
- Ammonolatory: The Life Element, late Prof. H. E. Armstrong, 134
- Amoebicides, Chemotherapy of, Dr. F. L. Pyman, 832
- Amphibian Anterior Pituitary, Gonadotropic activity of, Dr. H. Zwarenstein, 588
- Anabiosis and Fish Transport without Water, P. J. Schmidt and G. P. Platonov, 557
- d'analyse, Exercices, Prof. G. Julia. Rédigés par Dr. G. Bourion. Tome 4 (*Review*), 445
- Anaspidae, Embryology of the Crustacean, V. V. Hickman, 1018
- Ancient: Man in Devon, J. Reid Moir and Mr. and Mrs. MacAlpine Woods, 367; Monuments in France, 613; Civilizations, The Social Thought of the, Prof. Joyce O. Hertaler (*Review*), 914

- Androgenic Endocrine Activity in the Female Mammal, Prof. A. Lipchitz, 892
- Anglo-Egyptian Treaty Honours List, 310; -Saxon Silver Pennies, The Standard of, Ernest A. Smith, 1085
- Angmering Roman Villa, Appeal for funds for the Excavation of, 228
- Animal: Magnetism [1837], 476; Communities in Temperate America: as illustrated in the Chicago Region—a Study in Animal Ecology, V. E. Shelford (Review), 620; Geography, Ecological, Prof. R. Hesse. Prepared by W. O. Allee and K. P. Schmidt (Review), 620; Life, Wild, Conservation of, [Review], 1079; Year Book, The, Vol. 4. Edited by Dr. H. E. Bergmann (Review), 1079
- Animals, The Distribution of, Prof. J. Ritchie (Review), 620
- Anopheles gambiae* Giles, A Cage Colony of, B. de Maillon, 423
- Antarctic: Polychaetes, M. Pruvot, 647; Structure, S. E. Ross, 818; Surveys: Work of the "Discovery" investigations (Bruce memorial prize lecture), J. W. S. Marr, 868; vegetation, 936
- Anthropology: Applied, appointment of a standing committee on, 145; an Introduction to Primitive Culture, Prof. A. Goldenweiser (Review), 632
- Antirrhinum, Rust-resistant, D. E. Green, 73
- Anuran Gastrula, Ectoderm of the, Neural Induction by Fragments of Dead Tissue and Organs of Amphibia and Mammalia in the, Prof. G. A. Schmidt, 199
- Apophallus catus*, Life-history of, T. W. M. Cameron, 510
- Apoecetes*, Feeding Mechanism of, R. Dennell, 469
- Arabia, Archaeological Exploration in, H. St. John Philby, 885
- Archaeological: Excavations in Great Britain, Recent, 352; Reconnaissances in North-Western India and South-Eastern Iran, Sir Aural Stein (Review), 523; Evidence and 'Development', S. E. Winbolt, 764
- Archaeology, Racial Evolution and, Prof. H. J. Fleure (Huxley memorial lecture), 945, 981
- Archives, The Science of, in South Africa, Lt.-Col. O. G. Botha, 274
- Arctic: Weather Reports, 394; Racial History in the, Dr. A. Hrdlička, 577
- η Argus, Outburst of, Observed by Herschel, [1837], 1026
- Armstrong College, Research at, 273
- Aromatic Compounds, Antimicrobial Action of some, Dr. A. Girard, A. Ray and G. Richard, 283
- Arsine, Phosphine and, Derivatives of the Group I(b) Metals: Volatile Derivatives of Gold, Dr. F. G. Mann and A. F. Wells, 502
- Art and Artists, Primitive (Review), 619
- Asamayama, Magnetic Variation during an Explosion of, and its Mechanism, H. Nagaoaka and T. Ikebe, 695
- Ascorbic Acid: Specificity of Indophenol in the estimation of, in Fermented Products, F. W. Fox and W. Stone, 234; from Urine, Isolation of, Dr. O. P. Stewart, H. Scarborough and Dr. P. J. Drumm, 282
- Ash, Alkalinity of the, and loss of Chlorine on Incineration, F. Baerts and R. Vandewijer, 943
- Asiatic Flower-Birds and American Bird-Flowers, W. L. Van der Pijl, 775
- ASLIB List, New, 147
- Assam Origins in relation to Oceania, Dr. J. H. Hutton, 418; 487
- Astrology, The Science of (Review), 701
- Athenaeum*, The, and Meteorology [1837], 208
- Athens University, conferment of an honorary doctorate on Sir Napier Shaw, 104
- Atlantic: Air Mail Service, 56; Crossing, Fast, by Air, 581
- Atlantischen Ozeans, Temperatur, Salzgehalt und Dichte an der Oberfläche des, G. Böhnecke. Lief 1; Atlas (Review), 704
- Atmospheric: Pollution, Twenty-second report on, 101; Pressure at High Altitudes, Spectrum of Nitrogen and, R. Bernard, 980; Pollution, Conference on, 966
- Atomic: Spectra: and Atomic Structure, Prof. G. Herzberg. Translated by Prof. J. O. W. T. Spinks; Dr. S. Tulansky (Review), 626; and the Vector Model, A. O. Candler. 2 Vols. (Review), 626; Theory, Kelvin and the, O. Turnbull, 888; Constitution, Interpretations of, Lt.-Col. J. T. C. Moore-Brabazon, 893; Prof. E. N. da C. Andrade, 894; Constitution, Interpretations of, Lt.-Col. J. T. C. Moore-Brabazon, 971; Distances in Crystals, N. Elliott, 978; -Constitution, Interpretation of, Prof. A. S. Eve, 1061
- Augustus, Emperor, Bimillenary of the, 577
- Aurora Borealis [1837], 736; Rays, Divided, with One Part in the Sunlit and another in the Dark Atmosphere, Prof. O. Störmer, 1095
- Aurous Compounds: Constitution of, Gold Mirrors, Prof. O. S. Gibson, 533
- Australia: Scientific and Industrial Research, Council for, tenth annual report, 18; and New Zealand, Science in, 231; Bioclimatic Zones of, Dr. J. Davidson, 265; Aeronautical Research in, H. E. Wimperis Advising on, 722; Horticultural Research in, 843; Aborigines of, 1004; Administration and the, 1044
- Australian Aborigines, Representation of the, 798
- Australia's Burden, 1029
- Australopithecus*, Discovery of a Lower Molar of, Dr. R. Broom, 681
- Autobahn, The German, 926
- Automobile Engines in Theory, Design, Construction, Operation, Testing and Maintenance, A. W. Judge. Third edition (Review), 704
- Auxin: Effect of the Roots on the Production of, by the Coleoptile, J. van Overbeek, 293; Action of, on Protoplasmic Streaming, Prof. K. V. Thimann and Miss Beatrice M. Sweeney, 807
- Avebury, Scheme for the Preservation of, 144
- Axial Magnetic Suspension, Frictional Torque of an, Dr. J. T. Holmes and Prof. J. W. Beams, 30; Spin and Weapons of the Ancients, L. J. D. Richardson, 1016
- Azande, Witchcraft, Oracles and Magic Among the, Dr. E. E. Evans-Pritchard (Review), 338
- Azobenzene, The Cis-form of, G. S. Hartley, 281
- Azulene, Crystallised, Structure of, L. Misch and van der Wyk, 737
- β -Decay as Due to a Neutrino Shower, N. S. Nagendra Nath, 278
- β -Borwellinic Acid, Structure of, Dr. J. C. E. Simpson, 467
- β -Rays from Lithium and Boron Isotopes, D. S. Bayley and H. R. Crane; J. J. Turin and H. R. Crane, 776
- β -Braes, Transformation in, O. Sykes and H. Wilkinson, 857
- β -Phellandrene, Conversion of, into a Derivative of α -Phellandrene, Dr. N. F. Goodway and T. F. West, 934
- Babbage's "Bridgewater Treatise", [1837], 434
- Bacon Factory, Hygiene in the, 60
- Bacteria in the Old Sedimentary Rocks, New Data on the Existence of, L. Cayeux, 124
- Bacterial Suspensions, Optical Properties of, P. Bonét-Maury, 985
- Baffin Bay, Expedition to, 1937, 1083
- Ball Bearings, Miniature, 539
- Band Spectra, Vibration Temperature in Relation to Rotation Temperature in, Dr. N. R. Tawde and S. A. Trivedi, 463
- Bantu Blood Groups, Dr. R. Elsdon Dew, 77
- Barium, Surface Migration of, Dr. M. Benjamin and R. O. Jenkins, 152
- Battersea Power Station, 720
- B.D.H. Laboratory Chemicals, Catalogue of the, 808
- Beams Resting on a Yielding Foundation, Theory of, M. E. Reissner, 519
- Bee Research Committee, Dr. J. Anderson appointed representative of the Scottish Beekeeper's Association on the, 274
- Bees: Investigations, Brood Diseases of, Dr. Tarr, 578; Management of, [1837], 984
- Beit: Memorial Fellowships, elections to, 102; Fellowships for Scientific Research, award of, 148

- Belfast: Queen's University: conferment of an honorary doctorate on Prof. W. A. Osborne, 123; conferment of honorary doctorates on Dr. G. O. Anderson, Sir E. Farquhar Buzzard, Dr. H. Morley Fletcher, Prof. E. W. H. Groves, Prof. S. P. Bedson, and Dr. A. Felix, 166
- Belgian: Stratosphere Balloon Experiment, Dr. M. Cosyns, 54; Royal Academy of Sciences, award of the Gluge prize of physiology to Prof. J. J. Bouckaert, 274
- Belgique, Société Géologique de, Dr. L. J. Spencer elected a corresponding member of the, 190
- Bending Wood by Hand, Methods of, 977
- Benzanthrones, Synthesis of, F. G. Baddar and F. L. Warren, 321
- Benzene-Diazonium Chloride, Decomposition of, Dr. W. A. Waters, 466
- Bethlehem: Early Man at, Evidence of, 186; Ancient Fauna and Early Man at, 381; The Bone-bearing Beds of, their Fauna and Industry, Miss Elinor W. Gardner and Miss Dorothea M. A. Bate, 431; Flaked Flints from the Bone Beds of, Miss D. A. E. Garrod, 808
- Bialowieza National Park, Poland, Census of Game Animals in the, 358
- Biéla Comet, Disappearance of, J. Boaler and H. Roure, 40
- Binary: Mixtures, Viscosity of, Dr. J. S. Gourlay, 157; Orbits, Two Visual, Dr. R. v. d. R. Woolley and L. S. T. Symms, 160
- Biochemistry: Applied to Malting and Brewing, Prof. R. H. Hopkins and B. Krause (*Review*), 705; Annual Review of, Edited by Dr. J. M. Luck. Vol. 6 (*Review*), 745; Progress of (*Review*), 745
- Bioclimatic Zones of Australia, Dr. J. Davidson, 265
- Biological: Standards, 555; Laboratory Technique: An Introduction to Research in Embryology, Cytology and Histology, Prof. J. B. Gatenby (*Review*), 1081
- Biologischen Arbeitsmethoden, Handbuch der, Herausgegeben von Prof. E. Abderhalden. Lief. 460. Abt. V: Teil 10, Heft 6 (*Review*), 218
- Biology: General, Systematics in Relation to, 211; for Students of Pharmacy, E. J. Moore (*Review*), 633; Surface Action in, Prof. E. K. Rideal, 716; and the New Physics: a Plea for a Consistent Philosophy of Life, C. J. Bond (*Review*), 953; for Medical Students, O. O. Hentschel and Dr. W. R. I. Cook. Second edition (*Review*), 994
- Birch 'Forests' of Greenland, The, Dr. N. Polmin, 939
- Bird Life (*Review*), 1034; Protection in Britain, 1094
- Birds': British, "The Handbook of, H. F. Witherby, 199; Speed of Flight of, May Thacher Cooke, 325; Wild, and Butterflies, Dr. W. E. Collinge; Prof. G. D. Hale Carpenter, 974; of the Malay Peninsula, late H. C. Robinson and F. N. Chasen. Vol. 3: Sporting Birds; Birds of the Shore and Estuaries (*Review*), 1034; of the World, Check-List of, J. L. Peters. Vol. 3 (*Review*), 1034; The Book of, Edited by Dr. G. Grosvenor and Dr. A. Wetmore. 2 Vols. (*Review*), 1024
- Birmingham: Central Technical College, Dr. E. F. Armstrong awarded an honorary associatehip of the, 929; University: conferment of honorary doctorates on Lord Austin, Sir Harry Gilbert Barling, E. Cadbury, Sir Wilfrid Arthur Greene, Sir Percival Perry, and O. C. Paterson, 80; New Chemistry Laboratories, opening address by Sir Frederick Gowland Hopkins, 121; conferment of an honorary doctorate on C. C. Paterson, 351; Development of, 538; resignation of Sir Charles Grant Robertson, 694; conferment of an honorary doctorate on the Duke of Kent, 755; appointment of Dr. R. E. Priestley as vice-chancellor, 932, 942; retirement of G. O. Harrison, 1045; conferment of a doctorate on J. L. Shmwell, 1110
- Birth Control, Scientific Basis of, Dr. C. V. Drysdale, 19
- Bivalve Speifalls, Hydrography and Fisheries, Some Interrelations between, Prof. J. H. Orton, 505
- Blastoclada Fringsheimi, Germination of Resistant Spores of, Miss Elizabeth Blackwell, 933
- Blood: -Brotherhood in Dahomey, P. Hasomóné, 325; Smears, Supra-vital Stained, Method for Fixing Neutral-red in, A. Hjarre and H. Berthelsen, 155; Group A B, Races with a High Proportion of, Dr. R. Elsdon Dew, 1066
- Blow-fly Repellent, A New, H. O. Mönnig, 812
- Bodies for Dissection, Preservation of, [1837], 434
- Body Size and Metabolism, Relation between, O. Ellenby, 853
- Bogs at Ballybetagh, with Remarks on the Development of Late-Glacial Deposits in Ireland, J. Kissen and A. Farrington, 376
- Boissons, Les plantes à, Prof. D. Bois (Les plantes alimentaires chez tous les peuples et à travers les âges) (*Review*), 787
- Borine Carbonyl, A. B. Burg and H. I. Schlesinger, 74
- Boron: in the Potash Salts of Alsace, Presence and Distribution of, G. Bertrand, 820; in Agriculture, Miss Katherine Warrington, 1016
- Bororo, Clan Reciprocity Among the, C. Levi-Strauss, 429
- Botanical: Society: of Edinburgh, *Transactions and Proceedings* of the, 32, Part 1, 20; [1837], 208
- Botany, Medical, Advantages of, [1837], 904
- Bovine Congenital Porphyrinuria, Duality of the Coproporphyrins in, Dr. C. Rimington and G. C. S. Roets, 584
- Bradley's Zenith Sector Sent to the Cape [1837], 250
- Brasil, Caverns in, [1837], 655
- Breakers, Interpretation of Observations and Measurements Relating to, P. Pétry, 820
- Bremsstrahlung, On, J. C. Jaeger, 108
- Brisbane Seismological Station, 231
- Bristol University, resignation of Dr. E. Ashby, 904
- Britain: and the Beast, J. M. Keynes and others (*Review*), 623; Land of, Planning the, Dr. L. D. Stamp and others, 791; Early, Town Life in, Dr. R. E. Mortimer Wheeler (Norman Lockyer lecture), 924; The Hill Lands of, Development or Decay? Prof. R. G. Stapledon (*Review*), 1031
- British: Association: Nottingham meeting of the, 95; at Liverpool, [1837], 375; 434; at Nottingham; Lord Rayleigh elected president for 1938, 453; and the Indian Science Congress: a Scientific Delegation to India, 609; Seismological Committee, Report of the, 721; and the Indian Science Congress, 921; Astronomical Association, presentation of the Walter Goodacre gold medal and gift to Dr. A. C. D. Crommelin, 800; Chemical Manufacturers, Activities of the Association of, E. Wallace; Dr. F. H. Carr elected president, 719; Depopulation, The Menace of, Dr. G. F. McCleary (*Review*), 528; Empire Cancer Campaign, grants, etc. of the, 103; Medical Association, Belfast meeting of the, 186; Museum: (Natural History): Acquisitions at the, 18; Dr. F. W. Edwards appointed a deputy keeper in the department of entomology, 61; Acquisitions at the, 187; Acquisitions, 764; (Bloomsbury), Recent Acquisitions, 801; (Natural History), Catalogue of Fossil Cirripedia in the Department of Geology. Vol. 2: Oretaceous, T. H. Withers (*Review*), 873; Polar Year Expedition, Fort Rae, N.W. Canada, 1932-33. 2 Vols. (*Review*), 825; Rainfall, 1936 (*Review*), 873; School of Archaeology at Athens, 1935-36, 58; Museum: (Natural History), Acquisitions of the, 966; (Bloomsbury), Acquisitions at the, 1046; (Natural History), C. Forster Cooper appointed director, 967; Colonies, Introduction of Plants into, 1055; Institute of Radiology: Annual Congress and Exhibition, 1069; Archaeology, Cultural Successions in, 1109
- Brittany, A Mesolithic Site in, 329
- Broad Bean Plants in Water Culture, Effect of Heterosuxin on the Growth of, Dr. H. L. Pearce, 26
- Broadcasting in India, 614
- Bronze Age France, The Oolitic Limestone Escarpment in, Miss Margaret Dunlop, 243
- Brown-Firth Research Laboratories, Equipment and Work of the, 60
- Buenos Aires, Medical Association of Kinesiology, Prof. M. • Westenhofer elected an honorary member of the, 358

- Building Materials, Chemistry of, Dr. R. E. Stradling, 607
 Burial-Mounds of England, The Ancient, L. V. Grinell (Review), 218
 Business: Man's Library, A, 616; Administration, Tramping in, 1092
 Butterflies: Markings of, Chemical Development of the, W. Hüsslmayer, 41; Egg-laying, New Observations on Responses to Colours in, Dora Ilse, 544; Wild Birds and, Dr. W. E. Collinge; Prof. G. D. Hale Carpenter, 874
- CO Bands, Structure of a New System of, Dr. R. Schmid and Dr. L. Gerö, 508
 Cables for 200,000 Volt Pressures, 927
 Cadmium Nitride (Hydroxozote), Structure of, M. Basmère, 125
 Calcium: Bicarbonate in the Waters of the River Versoix (Canton of Geneva), Origin of the, J. P. Buffle, 125; Phosphorus and, Deficiency Diseases as Two Ethnologically Distinct Entities, Dr. P. J. Du Toit and Dr. A. I. Malan, 153
 Calculus, Theory and Practice of the, Dr. A. J. Ward (Review), 831
 Calcutta: University College of Science, retirement of Sir P. O. Ráy; election of Sir P. O. Ráy as professor emeritus, 762
 California: Sardine and its Fishery, Frances N. Clark, 858; Northern, Earthquakes off the Coast of, Prof. Byerly, 937
 Calomel Vapour, Nature of, F. T. Gucker, jun., and R. H. Munch, 648
 Cambridge: Philosophical Society, election of officers, 888; University: Dr. H. J. Bhabha awarded an 1851 exhibition studentship; Dr. C. F. A. Pantin to be appointed reader in invertebrate zoology; Dr. R. D. Davies elected a research fellow of Christ's College; Sir David Chadwick elected an honorary fellow of Sidney Sussex College, 88, 80; Dr. A. D. Thackeray appointed assistant director of the Solar Physics Observatory, 80; Dr. O. M. B. Bulman appointed lecturer in paleozoology, Dr. J. K. S. St. Joseph demonstrator in geology, M. Black demonstrator in geology, J. D. Boyd lecturer in anatomy, Dr. W. A. H. Rushton lecturer in physiology, S. J. R. Reynolds and O. D. P. Jones demonstrators in anatomy, A. L. Hodgkin demonstrator in physiology, and Dr. G. N. Myers demonstrator in pharmacology, 123; A. M. Barry appointed a Frank Edward Elmore student, and B. G. Wilkinson and M. G. M. Pryor awarded Frank Smart prizes, 123; Early Science in, Dr. R. T. Gunther (Review), 180; Dr. J. H. Schulman appointed assistant director of research in colloid science; D. J. Bauer elected Michael Foster student in physiology; award of the E. G. Fearnsides scholarship to A. M. Barry, the Wrenbury scholarship to J. T. Bauer, and the John Winbolt prize to D. W. Gibbs, 391; K. P. Harrison and O. L. Kangwill awarded Harold Fry studentships at King's College; J. V. Dunworth and T. E. Easterfield awarded Denman Baynes research studentships at Clare College; A. G. Ward awarded an external research studentship at Emmanuel College, 435; T. R. O. Fox and J. Diamond appointed demonstrators in engineering; Dr. R. A. Lyttleton and M. H. L. Price appointed faculty assistant lecturer in mathematics; J. Hart-Mercer elected Gwyneth Pretty student and Nita King scholar; R. E. B. Makinson awarded a Strathcona exhibition for physics at St. John's College, and J. H. Sang a Hutchinson studentship for zoology, 476; G. Metcalfe appointed Frank Smart student in botany; G. S. Gough, O. H. Bamford and D. M. A. Leggett elected fellows of Trinity College; bequest by W. O. Wilson, 735; R. L. M. Synge appointed Benn W. Levy student in biochemistry: grants from the Balfour Fund; conferment of a degree on Prof. T. Dalling, 778; Dr. H. Brück appointed first junior observer in the Solar Physics Observatory; Miss M. L. Tomlinson elected a staff fellow of Girton College, 819; gifts from J. W. O. Hamilton for radio research, 862; portraits of Sir Albert Seward and Dr. F. F. Blackman presented to the Botany School, 845; G. L. Clark elected an Isaac Newton student; Dr. O. F. A. Pantin appointed reader in invertebrate zoology, T. T. Paterson curator of the Museum of Archaeology and of Ethnology, Dr. J. A. Ramsay, Harding lecturer in experimental zoology, Dr. G. S. Carter, F. R. Parington and Dr. G. Salt lecturers in zoology, 904; Prof. E. Örtén appointed Rouse Ball lecturer for 1937-38; Prof. M. Siegbahn appointed Scott lecturer for 1938-39; gift for the Experimental Zoology Fund; H. O. Gilson and Dr. S. Smith appointed demonstrators in zoology and Prof. S. Chapman a member of the Committee for Geodesy and Geophysics, 1026; conferment of a doctorate on W. G. Palmer, 1110
 Cambium Tissue, Culture of, R. Gautheret, 905
 Canada: Engineering Institute of, election as honorary members of Sir Alexander Gibb, Hon. C. D. Howe, Hon. G. Stirling, Prof. R. W. Angus, Dr. G. H. Duggan, and S. J. Hungerford, 274; Royal Society of, Annual Meeting; award of the Flavelle medal to Dr. F. D. Adams, the Lorne Pierce medal to Prof. S. Leacock, and the Tyrrell medal to A. Fauteux; Prof. A. G. Huntsman elected president for 1937-38, 287; Mining Industry of, C. Camell, 542; Petroleum Fuels in, 978
 Canadian Shield, Gold Deposits of the, E. L. Bruce, 116
 Cancer: Memorandum on Provision of Radio-Therapeutic Departments in General Hospitals, Lt.-Col. Smallman, 356
 Candle, Death in the, [1837], 39
 Cannizzaro Reaction: Catalysis of the, by Active Nickel and Platinum, M. Delépine and A. Horeau, 208; Bonhoeffer and Fredenhagen, 369
 Canoes of Polynesia, Fiji and Micronesia, J. Hornell, 510
 Cape Town University, Prof. A. W. Falconer appointed principal and vice-chancellor, 478
 Car, Maintenance and Repair, A. W. Judge. Second edition (Review), 704
 Carbohydrates *in vitro*, Photosynthesis of, Prof. E. C. C. Baly, 930
 Carbon: Monoxide, Hydrogen and Oxygen, Heterogeneous Combustion of Mixtures of, on a Vitreous Surface, M. Prettre, 251; Carbon Bond Distances, L. Pauling and L. O. Brookway, 688; Dioxide, Vibrational Energy of, Determination of the Relaxation Time for the, Prof. A. van Isterbeek and P. Mariña, 850; Disulphide, Infra-red Absorption of, O. R. Bailey, 861; Suboxide, Structure of, Dr. R. C. Lord and Dr. A. Wright, 856; Atomic Weight of, A. F. Scott and F. M. Hurley, 1068; Monoxide Mixtures, Influence of Hydrogen and Water Vapour upon the Combustion of, Prof. W. T. David and B. Fugh, 1098
 Carborandum, Ultra-filters of, J. Duclaux and M. Amat, 658
 Carcinogenic Agents, Photodynamic Action of, Dr. J. O. Mottram and Dr. I. Doniach, 933
 Caribbean Sea, Cyclone Series in the, October 17-24, 1935, E. Kidson, 286
 Carlsberg Ridge, Basalts from the, Dr. J. D. H. Wiseman, 855
 Carnegie: Institution of Washington, Report for year ending October 31, 1936, 247; United Kingdom Trust, Report for 1936, 541; Catalogue of Publications of the, 1094
 Carotenoids and other Lipoid-soluble Pigments in the Sea and in Deep Marine Mud, D. L. Fox, 519
 Cartesian Diver, Principle of the, Applied to Gasometric Technique, Dr. K. Linderström-Lang, 108
 Cartography, 460
 Caspian Sea, Level of the, [1837], 942
 Catalytic: Action of Surfaces, The, Dr. J. E. Nyrop. Second edition (Review), 827; Reactions, Dr. H. W. Melville (Review), 827
 Catechol Ethers, Derivatives of Higher, G. K. Hughes and F. Lions, 685

- Caterpillar Plagues in Great Britain, Recent, 94
 Catgut for Surgical Use, Safe, 1094
 Cathode : Sputtering, Controlled, Dr. G. Timoshenko, 67 ;
 Ray Tube : The Low Voltage, and its Applications,
 G. Parr (*Review*), 1032
Cases and Curing, No. 1, 186
 Cell : Walls, Lignified, Histochemical Study of, J. Kisser
 and K. Lohwag, 335 ; Division, Radiation and,
 Tanale, Spear and Gluckmann, 686 ; Nucleus and
 Cytoplasm, Interaction between, Prof. O. Stern, 770 ;
 Dr. O. D. Darlington, 932
 Cells, Respiring, Prevention of Assimilation in, Dr. O. E.
 Clifton, 318
 Cellulose : Hydrate, Transformation of, into Native
 Cellulose, Prof. K. H. Meyer and N. P. Badenhuizen,
 jun., 281 ; Starch and Glycogen, Prof. H. Staudinger,
 1071
 Cementite, Pure, Isolation of, by Acid Attack of Ferrous
 Materials and on Some Physical Properties of this
 Body, A. Travers and R. Diebold, 1073
 Cements, Hydraulic, Dr. F. M. Lee, 899
 Central : Nervous System, Choline Esterase in the, D.
 Nachmansohn, 427 ; (Native) Medical School, Suva,
 Fiji, The, Sir James Barrett, 472
 Cepheid Variables, Maintenance of the Pulsation in, Dr. J.
 Woltjer, jun., 195
 Cereal Crosses, Reciprocal, Endosperm and Embryo in,
 J. W. Boyes and W. P. Thompson, 511
 Charcoal, Activated, Adsorption of Gases and Vapours on,
 R. Juxa and Langheim, 649
 Chatham House, Prof. A. G. B. Fisher appointed Price
 professor of international economics at, 143
 Chemical : Industry : Society of, Food Group, 20 ;
 Science, A Retrospect of, Prof. G. G. Henderson,
 145 ; Society of Stockholm, award of the Scheele
 medal to Dr. A. Butenandt, 274 ; Reactions : Re-
 tardation of, Prof. K. C. Bailey and G. T. Taylor, 327 ;
 The Retardation of, Prof. K. C. Bailey (*Review*),
 340 ; Stabilization, Prof. N. R. Dhar (*Review*), 340 ;
 Anniversaries, Daily, As a Teaching Tool, E. H.
 Huntress, 616 ; Engineering Congress of the World
 Power Conference, Transactions of the 5 Vols.
 (*Review*), 627 ; Engineering : Position and Prospects
 (*Review*), 627 ; Principles, with Particular Applica-
 tion to Qualitative Analysis, Prof. J. H. Yoe (*Review*),
 634 ; Industry : French Society of, Seventeenth
 Congress in Paris, 672 ; Research, Dr. I. Langmuir,
 901 ; Changes and Chances, Sir Martin Forster
 (Streetfield memorial lecture), 1055 ; Encyclopædia,
 A (*Review*), 1076
 Chemicals in War : a Treatise on Chemical Warfare,
 Dr. A. M. Prentiss. With chapters on the protection
 of Civil Populations and International Situation, by
 Major G. J. B. Fisher (*Review*), 3
 Chemie : Lehrbuch der, Prof. W. Hückel. Teil 2. Organische
 Chemie (*Review*), 868 ; Anorganischen, Handbuch der,
 Herausgegeben von Prof. R. Abegg, Dr. F. Auerbach
 und Dr. I. Koppell. Band 4. Abt. 3. Teil 4, Lief 1,
 Herausgegeben von Dr. I. Koppell (*Review*), 1081
 Chemistry : Progress of, Annual Reports on the, for
 1936. Vol. 33 (*Review*), 7 ; Applied, Reports of the
 Progress of, Vol. 21, 1936 (*Review*), 49 ; of Indian
 Opium, Dr. H. B. Dunnilliff, 92 ; Elementary, and
 its Presentation, Prof. O. S. Gibson (*Review*), 173 ;
 New Practical, Fundamental Principles Applied to
 Modern Life, Prof. N. H. Black and J. B. Conant
 (*Review*), 173 ; Practical, New Laboratory Experi-
 ments in, Prof. N. H. Black (*Review*), 173 ; A Brief
 Outline of its History and Development, A. Barclay,
 232 ; for Everyman, Prof. A. Findlay (*Review*), 300 ;
 Matter and Life, Dr. S. Miall and L. M. Miall (*Review*),
 300 ; Inorganic, A Text-book of, Edited by Dr. J.
 Newton Friend. Vol. XI, Part 4, by A. E. Goddard
 (*Review*), 528 ; of Building Materials, Dr. R. E.
 Stradling and others, 607 ; A Hundred Years of,
 Prof. A. Findlay (*Review*), 624 ; Modern, The Growth
 of, Prof. J. Read (*Review*), 624 ; Organic, Practical,
 A. J. Mee (*Review*), 634 ; Quantitative Pharma-
 ceutical, Prof. G. L. Jenkins and Prof. A. G. Du Mes.
 Second edition (*Review*), 634 ; The Drama of, How
 Man Deals with Atoms, Prof. S. J. French (*Review*),
 634 ; of Natural Products Related to Phenanthrene,
 The, Prof. L. F. Fieser. Second edition (*Review*),
 704 ; Mineral, and Crystal Structure, Prof. P. Niggl
 (*Review*), 783 ; Organic : A Survey of, Prof. O. S.
 Gibson (*Review*), 868 ; Synthetic, Recent Progress
 in, Dr. G. O. Curme, jun., 901 ; Intermediate, late
 Prof. T. M. Lowry and A. O. Cavell ; Prof. H. V. A.
 Briscoe (*Review*), 910 ; Enzyme, Dr. H. Tauber
 (*Review*), 948 ; in the Ancient World, Prof. J. R.
 Partington (Bedson lecture), 1006 ; Applied, Thorpe's
 Dictionary of, Prof. J. F. Thorpe and Dr. M. A.
 Whiteley. Fourth edition. Vol 1 (*Review*), 1076
 Chemotherapy, Researches in, Dr. F. L. Pyman, 409
 Cherries, Sweet, Incompatibility and Sterility in, M. B.
 Crane and A. G. Brown, 1019
 Cherry Trees, Bacteriosis of, H. Wormald, 285
 Cheshunt Research Station, Annual Report for 1936,
 860
 Chicken Retina : Carotenoids of the, G. Wald and H.
 Zeman, 197 ; Photo-labile Pigments of the, Dr. G.
 Wald, 545
 Chickens, Hatching Weight of, Factors Affecting, N.
 Galpin, 1027
 Chile, Ancient Man in, 538
 China : Medical Mission to, [1837], 598 ; European
 Botanical Discoveries in, History of, F. O. Stern,
 1098
 Chinese : Ceramic Glasses, A. L. Hetherington (*Review*),
 882 ; Bronzes, Early, R. S. Jenyns, 591 ; Centres of
 Learning, Destruction of, 925

 Light: The Neutrino Theory of, V. Fock, 113; Neutrino Theory of, in Three Dimensions, A. Sokolow, 810; thought to have been seen in the neighbourhood of Alternate Current Magnets, The, Lord Rayleigh, 423; Diffraction of, by Ultrasonics at Oblique Incidence, Dr. F. Levi, 969
 Lightning Discharges, Effect of near, on a Magnetometer, Dr. K. R. Ramanathan, 587
 Liquid Drops at Interfaces, Visible Adsorbed Films and the spreading of, Prof. D. H. Bangham, S. Moosallam and Z. Saweris, 237
 Liver, Fatty, Action of Pancreatic Extract on, B. Shapiro and Prof. E. Wertheimer, 771
 Locusts in the Field, Phase transformation in, J. S. Kennedy, 889
 Louse, Biting-, Distribution of the, N. J. B. Plomley and G. B. Thompson, 199
 Low-Temperature Thermostat, An inexpensive, L. C. Beadle and F. A. Booth, 279
 Lysosyme, Crystallization of, E. P. Abraham and Prof. R. Robinson, 24
 Magnetic Storms: Cosmic Rays and, Prof. S. Chapman, 423; Variations of Cosmic Ray Intensity during, Prof. O. Störmer, 549
 Meiosis and Mitosis, Artificial release of Crossing-over in, Prof. H. Friesen, 362
M-Emission Bands of Zinc, Copper and Nickel, Dr. H. W. B. Skinner and J. E. Johnston, 508
 Mental: Factors, Selection and, Dr. G. H. Thomson, 934; Disturbances, Physiological Patterns and, J. W. Thompson, W. Corwin and J. H. Aste-Salas, 1062
 Merino, Trio Follicles in the, Non-specificity of the, Dr. A. B. Wildman, 891
 Mesothorium-I, Concentration of, by Duckweed (*Lemna*), Prof. W. I. Vernadsky, B. K. Brunowsky, and O. G. Kunaheva, 317
 Metal Films, Thin, Structure and Resistance of, D. A. Wright, 107
 Metals: Rigidity of, Effect of Occluded Hydrogen on the, Father J. Lynch, 363; Oxide Film Formation on, Polarimetric studies of, A. B. Winterbottom, 364; of Hexagonal Structure, Asymmetry in, Dr. G. W. Brindley and P. Ridley, 461; Ferromagnetic, The Paramagnetic Magnetron Numbers of the, Prof. W. Suksmith and R. R. Pearce, 970; Structure of, Dr. A. Müller, 1011
 Metabolism, Size and, Relation between, O. Ellenby, 853
 Metaphosphoric Acid, Reaction between Proteins and, Dr. H. Herrmann and G. Perlmann, 807
 Meteor, Bright, of November 9, A. E. Moon, 1102
 Meteorites: The number of Pultusk Stones, and the spelling of "Widmanstätten Figures", Prof. F. A. Paneth, 504; 809; Dr. L. J. Spencer, 589
 Methyl Halides, Carbon-Halogen Distance in the, Dr. G. B. B. M. Sutherland, 239
 Mice, Sensitization of the Skin of, to Light by Carcinogenic Agents, Dr. I. Doniach and Dr. J. O. Mottram, 588
 Milk, Off-flavoured, Acidosis and, Capt. H. Barkworth and L. W. L. Cole, 324
 Mitosis, Meiosis and, Artificial release of Crossing-over in, Prof. H. Friesen, 363
 Mitotic Spindle, Self-arrangement in the, under Mechanical Influence, Dr. H. E. Pfeiffer, 770
 Molecular: Compounds, Organic, Structure of, Dr. J. S. Anderson, 583; Structure, Force Constants and, Dr. H. W. Thompson and J. W. Linnett, 1065
 Molybdenum, Tellurium, Tungsten and, Hexaco-ordination of, J. Gupta, 685
 Monomolecular Films, Viscosity of, Prof. W. D. Harkins and R. J. Myers, 465
 Nd⁺⁺⁺ Ion, Absorption Spectra evidence of the Decomposition of the Ground Term of, due to Crystalline Fields, Prof. D. M. Bose; Dr. W. G. Penney and G. J. Kynch, 109
 Nematodes, Physiology of, D. G. Davey, 645
 Neural: Induction by Fragments of Dead Tissues and Organs of Amphibia and Mammalia in the Ectoderm of the Anuran Gastrula, Prof. G. A. Schmidt, 199; Induction by Plant Tissues in the Ectoderm of the Gastrula of *Triton taeniatus*, M. N. Ragozina, 199
 Neutrino: Theory of Light, The, V. Fock, 113; Shower, β -Decay as due to a, N. S. Nagendra Nath, 278; Theory of Light in Three Dimensions, A. Sokolow, 810
 Neutron: Beams, Polarized, A method of obtaining, Dr. H. v. Halban, jun., 425; Levels, Resonance, of Silver, Rhodium and Bromine Nuclei, Spacing of the, C. Y. Chao and T. H. Wang, 768
 Neutrons: Production of Mutations by, Mary Nagai and G. L. Locher, 111; Expulsion of, from Lead by Cosmic Rays, B. Arakatsu, K. Kimura and Y. Uemura, 277; inside Magnetized Iron, The Magnetic Field acting upon, Dr. O. R. Frisch, Dr. H. von Halban, jun., and Dr. J. Koch, 360; Slow, Capture of, in Light Elements, Dr. O. R. Frisch, Dr. H. von Halban, jun., and Dr. J. Koch, 895
 Nickel Wire, Magnetic Quality of, as influenced by the Surface, Dr. T. F. Wall, 238
 Nile, Dry Crossing of the, E. J. Wayland, 811
 Nitric Oxide and Alkyl Ethers, Prof. M. W. Travers, 107
 Nitrogen: Excretion of, by Leguminous Plants, Prof. P. W. Wilson, 154; Prof. A. I. Virtanen; Dr. G. Bond, 683; Spectrum of, and Atmospheric Pressure at High Altitudes, R. Bernard, 930
 Nuclear Particles, Interaction of, Dr. N. Kemmer, 192
 Octadiol Monobenzoate, Inhibition by the Response of the Pigeon Crop Gland to Prolactin: Dr. S. J. Folley and P. White, 505
 Oestrous Reactions, including Mating, produced by Triphenyl Ethylene, J. M. Robson and Dr. A. Schonberg, 196
 O₂⁺ Bands, Visible, Rotational Analysis of the, T. E. Nevin, 1101
 O-H Raman Frequency in Inorganic Acids, The, Dr. C. S. Venkateswaran, 151
 Oil Drops, Collision of Two, and the Stability of a Non-spherical Oil Drop, Yoshio Ishida, 70
 Optical Contact, Propagation of, Dr. J. Weir French, 321; Sensitizing of Silver Halides by Dyes, Mechanism of, Dr. S. E. Sheppard, Dr. R. H. Lambert and R. D. Walker, 1096
 Oxidation Catalyst, A New, J. G. Dewan and D. E. Green, 1097
 Oxide Film Formation on Metals, Polarimetric studies of, A. B. Winterbottom, 364
 Oxides formed on Iron, Electron Diffraction studies of, T. Iimori, 278
 Oxonium Compounds, Raman Spectra of, Dr. G. Briegleb and W. L. Lauppe, 236
 Oxygen in Sea Water, Consumption of, under Controlled Laboratory Conditions, H. R. Serwell, 508
 Oxyporphyrin Haematin Compound, An, as intermediate between Protohaematin and Verdohaematin, Dr. R. Lemberg, B. Cortis-Jones and M. Norris, 65
 Oyster and the Salmon, Sex-Biology of the, Prof. J. H. Orton, 68
 Pacific Seismological Stations, Reliability of, Dr. H. Jeffreys, 237
 Pancreatic Extract, Action of, on Fatty Liver, B. Shapiro and Prof. E. Wertheimer, 771
 Papein, Natural Activation of, Prof. M. Frankel and R. Mamm, 1016
 Para-Cresol from the Urine of Pregnant Mares, Dr. P. G. Marshall, 362
 Pentaerythritol, Solid, Hydrogen Bridges in, I. Nitta and T. Watanabe, 365
 Personnel Organization, A Psycho-geometrical Representation of, W. R. Dunlop, 152
 Phosphate in Muscle, Coupling of Disputations with Esterification of, Dr. Dorothy M. Needham and R. K. Pillai, 65

- Phosphine and Arsenic derivatives of the Group I(b) Metals : Volatile derivatives of Gold, Drs. F. G. Mann and A. F. Wells, 502
- Phosphorus : and Calcium Deficiency Diseases as two Etiologically Distinct Entities, Dr. P. J. Du Toit and Dr. A. I. Malan, 153; Exchange in Yeast, Prof. G. Hevesy, Dr. K. Linderstrom-Lang and N. Nielsen, 725
- Photographic Plates, Sensitized, Position of Maximum Optical Sensitivity of, S. Natanson, 197
- Photoperiodic After-Effect, Prof. R. H. Stoughton and D. R. Hale, 808

- Kiel University, Dr. W. Kuhn appointed professor of physical chemistry in, 358
- Kinematography, Fifth Annual Exhibition of, 964
- Kinases, Taxes and, Classification of, Dr. D. L. Gunn, J. S. Kennedy and D. P. Pielou, 1064
- Komodo 'Dragons' at Edinburgh Zoological Park, 721
- Krypton and Xenon, Packing Fractions of, Dr. F. W. Aston, 149
- Kxatla Culture, Modern, Contributions of Western Civilization to, Prof. I. Schapera, 16
- L* α Emission Lines of Cu and Fe, Intensity and Structure Changes of the, on intense Cooling of their Anticathodes, Prof. K. Pross and A. T. Maitra, 464
- L*-Emission Bands of Zinc, Copper, Nickel and Cobalt, Dr. J. Farinau, 508
- Li⁺ and He, Ionization Energy of, H. A. S. Eriksson, 181
- Labour, Displacement of, by Machinery, H. D. Henderson, 679
- Lac in Malaya, N. C. E. Miller, 510
- Lactoflavin: in Milk, Determination of, C. H. Whittnah, B. L. Kumerth and M. M. Kramer, 430; The Coulter Compound, 'Cytochrome *b*', and Cytochrome *c*, Spectroscopic observations of reactions between, Prof. F. Urban and Dr. M. D. Eaton, 466
- Lake District as a National Park, The, 433
- Lamellibranch Gills, Ciliary Currents in, A. Graham, 687
- Land: Drainage: Act, 1930, Report on, 823; in England and Wales, 823; Speed Record, New World, Capt. G. E. T. Eyston, 929; for the People (*Review*), 1031
- Langmuir-Blodgett Films of Stearic Acid, Structure of, L. H. Germer and K. H. Stork, 779
- Language in Europe: Borderlands of, and their Relation to the Historic Frontier of Christendom, Dr. Vaughan Cornish (*Review*), 994

- Lanckester, Ray, Investigator, at Plymouth, Dr. S. Ochoa appointed, 190
- Lantern Slides, German and British, 718
- Larvae in Timber, Destructive, Detection of, Dr. R. L. Smith-Rose, 512
- Latin Clarity and the Sciences of Life, Dr. J. Needham (*Review*), 664
- Lead: Borates, R. F. Geller and E. N. Bunting, 34; A New Oxide of, O. Holtermann and P. Laffitte, 293; Crystal Growths in Silica Gel, Spiriform Morphology of some, N. Stuart, 539; Ores, Origin of, Prof. A. Holmes, 937
- League of Nations, Health Committee of the, Dr. T. Madsen re-elected president of the, 315
- Learning, The Higher, Dr. R. O. Wallace, 541
- Leather Trades' Chemists: International Society of, Conference at Copenhagen, 516
- Lekistes, Succession Broods of, G. L. Purser, 155; Dr. O. Winge, 487
- Leicithin, Yolk, Origin of, L. Hahn and Prof. G. Hevery, 1059
- Lectionem following the Administration of Fat, Prof. G. Hevery and E. Lundegaard, 275
- Leeds University: endowment of the Olive Behrens lectureship, Hon. Mrs. Behrens, 166; conferment of title of emeritus professor on Dr. G. W. Watson, 778; scheme for promotion of physical fitness, 886; Dr. J. W. Orr elected reader in experimental pathology; Dr. H. G. Garland appointed clinical lecturer in medicine and honorary demonstrator in medical pathology, Dr. J. A. Price honorary demonstrator in medicine, N. Lissimore honorary demonstrator in pathology, F. R. W. Hensley and I. J. Keadan honorary demonstrators in anatomy and Miss Florence O. Bell research assistant in textile physics, 943
- Legendre Functions, Zeros of, P. G. Gormley, 81
- Légion d'Honneur, La Croix de Chevalier de la, conferment of, on G. E. Pearson, 315
- Legumes and Non-legumes, Associated growth of, A. I. Virtanen, 248
- Leicester, Roman, Excavation of, 229
- Leisure: Utilization of, Survey on the, 229; The Problem of, 941
- Lemna minor, A Short Periodic Growth Cycle and a Secular Variation in, H. Dickson, 112
- Leopold, Order of, Profs. J. Bordet and P. Nolf awarded the Grand Cross of the, 104
- Lepidosiren, Cytology of, Prof. W. E. Agar, 931; Prof. E. W. MacBride, 932
- Leukemia in Mice, Inheritance of, Dr. E. O. MacDowell, 368
- Leverhulme Research Fellowships, and Research Grants, award of, 102
- Leviathan, The (*Review*), 911
- Lhwyd's Maps of England and Wales, Dr. F. J. North, 813
- Lichens found in Ireland—Chemical Constituents of: *Periularia concolor*, J. Breen, J. Keane and T. J. Nolan, 333; *Parmelia conspersa*, Ach, Margaret Mohan, J. Keane and T. J. Nolan, 376
- Life: Here and Now: Conclusions derived from an Examination of the Sense of Duration, Arthur Ponsonby (Lord Ponsonby of Shulbrede), (*Review*), 341; Reflections on, R. Brightman (*Review*), 341; The Little Things in, the Vitamins, Hormones and other minute Essentials for Health, Prof. B. Sure (*Review*), 829
- Light: the Neutrino Theory of, V. Fock, 113; Anomalies of the Dispersion of, by Colloidal solutions of Silver, O. Janneran, 209; Depolarization of, diffused by Argon, New Measurements of the Factor of, A. Rousset, 251; thought to have been seen in the neighbourhood of Alternate Current Magnets, The, Lord Rayleigh, 433; in the Service of Man, Prof. N. R. Dhar (*Review*), 444; Sources, High Intensity, Dr. J. A. V. Fairbrother, 552; Neutrino Theory of, in Three Dimensions, A. Sokolow, 810; Diffraction of, by Ultrasonics at Oblique Incidence, Dr. F. Levi, 969
- Lighting: Appraisement of, Dr. C. O. Paterson (Guthrie lecture), 763; in Factories and Workshops, Appointment of a committee on, 845; Public, Control of, 1090
- Lightning: Discharges, Effect of near, on a Magnetometer, Dr. K. R. Ramanathan, 587; Ball, A Theory of, T. Neugebauer, 814
- Lilium Harrisii, Bud Development in, following treatment with Indoleacetic Acid, J. M. Beal, 519
- Linear Operators: The Theory of, from the Standpoint of Differential Equations of Infinite Order, H. T. Davis (*Review*), 174
- Linguistics, Contemporary, The Dilemma of, Prof. B. Malinowski (*Review*), 173
- Lipids, The Biochemistry of the, Dr. H. B. Bull (*Review*), 787
- Liquid: Drops at Interfaces, Visible Adsorbed Films and the Spreading of, Prof. D. H. Bangham, S. Mosallam and Z. Sawaris, 237; Hydrocarbons, Light, Products Formed by the Incomplete Combustion of, A. Maillard and R. Friedrich, 985
- Liquids, Natural Convection in, M. Atanasiu, 985
- Lister Institute of Preventive Medicine, Forty-third annual report, 766
- Liver, Fatty, Action of Pancreatic Extract on, B. Shapiro and Prof. E. Wertheimer, 771
- Liverpool Naturalists' Field Club, Seventy-sixth annual proceedings of the, 357
- Liverpool, S.S., Launch of [1837], 693
- Living World, The (*Review*), 484
- Lockyer, Norman, Observatory, Annual Report, 1936-37, 965
- Locust Outbreak in Africa and Western Asia, Fifth survey of the, Dr. B. P. Uvarov and Miss W. Milnthorpe, 33
- Locusts in the Field, Phase Transformation in, J. S. Kennedy, 839
- Logic and Empiricism, Dr. T. Greenwood (*Review*), 866
- Lomonosov and Early Science in Russia, S. S. Ivanoff (*Review*), 784
- Lomonosova, Trudy M. V., po Fizike i Khimii, Prof. B. N. Menshutkin (*Review*), 784
- London: Electrical Society [1837], 208; University: award of postgraduate studentships; J. P. Quilliam awarded a university studentship in physiology; O. A. Saunders appointed Clothworkers' reader in applied thermodynamics at the Imperial College—City and Guilds College, 38; A. A. Miles appointed professor of bacteriology at University College Hospital Medical School and Prof. J. H. Dible professor of pathology at the British Postgraduate Medical School, 186; Sir Robert Pickard elected vice-chancellor and Prof. J. O. Phillip deputy vice-chancellor; Dr. W. Wardlaw appointed professor of physical chemistry at Birkbeck College; conferment of title of professor on Dr. G. R. Cameron and that of reader on H. Torrey, 207; T. O. Stamp appointed reader in bacteriology at the British Postgraduate Medical School; Dr. A. R. Todd appointed reader in biochemistry at the Lister Institute of Preventive Medicine; conferment of the title of reader in zoology on H. R. Hewer and that of emeritus professor on Prof. H. V. Blackman; gift by A. Chester Beatty for a scholarship in radiology, 778; conferment of an honorary doctorate on the Queen, 862; J. D. Bernal appointed professor of physics at Birkbeck College, 904; Prof. A. J. Allmand appointed Daniell professor of chemistry at King's College, Dr. L. P. Garrod reader in bacteriology at St. Bartholomew's Hospital Medical College, Dr. O. F. Goodeve reader in chemistry, O. W. Dannatt reader in metallurgy at the Imperial College—Royal School of Mines and Dr. H. J. T. Ellingham reader in physical chemistry at the Imperial College of Science and Technology, 942; College: Prof. J. B. S. Haldane first holder of the chair of biometry, 612; Prof. S. Sugden appointed professor of chemistry and Prof. O. K. Ingold director of the Chemistry Laboratories, 654; conferment

- upon Prof. T. Yeates, of the title of emeritus professor, 1020; New buildings for, 1088; conferment of the title of reader in civil engineering on Dr. A. L. Higgins, and that of emeritus professor of chemistry on Prof. F. G. Donnan; award of a doctorate on Miss Katherine Warington and Miss Katherine Tansley, 1110; College, Extension of Buildings, 984; Mathematical Society, election of officers, 1094
- Long Ashton Research Station, Annual Report for 1936, 861; Barrow, Origin of the, S. Piggott, 1103
- Longitudes, An Annual Change in, Dr. F. Schlesinger, 1068
- Loris: a Journal of Ceylon Wild Life, 720
- Louse, Biting, Distribution of the, N. J. B. Plomley and G. B. Thompson, 199
- Low-Temperature Thermostat, An inexpensive, L. C. Beadle and F. A. Booth, 279
- Lubrication and Lubricants, 815; 859
- Lubricants, Lubrication and, 815; 859
- Lyall: in Germany [1837], 378; to Leonard Horner [1837], 517
- Lymnaea, *Drosophila* and, Temperature and the Growth of, T. Imai, 1067
- Lysosyme, Crystallisation of, E. P. Abraham and Prof. R. Robinson, 24
- M-Emission Bands of Zinc, Copper and Nickel, Dr. H. W. B. Skinner and J. E. Johnston, 508
- Mackintosh, Dr. John [1837], 786
- Magma, Das, und seine Produkte. Teil 1: Physikalisch-chemische Grundlagen, Prof. P. Niggli (*Review*), 913
- Magmatic Differentiation, Dr. C. N. Fenner, 327
- Magnetic: Declination at Orsoy during the period 1914-36, A. Kania, 335; Storms: Cosmic Rays and, Prof. S. Chapman, 423; Variations of Cosmic Ray Intensity during, Prof. C. Störmer, 549; Permeability, Effect of Surface Treatment on, Dr. T. F. Wall, 856; Observations in America [1837], 904
- Magnesium: Alloys, H. Endô and S. Morioka, 978; Chloride with Oxygenated Organic Compounds, Classification into two Groups of the Complex Compounds of, According to the Nature of the Oxygen Linkage, Mlle. Marie Louise Quinet, 985
- Magneto-Electric Currents [1837], 250
- Magnetostriiction, Dr. Y. Mamiyama, 552; W. Alexander and J. Swaffield, 1068
- Malden Castle, Dorchester: Excavations in 1937, 186; Discoveries at, 677
- Malaya: Forestry Research in, 1091; Rubber Research Institute, Report for 1936, 1093
- Malayan Agriculture, An Outline of, D. H. Grist (*Review*), 7
- Mammals: and Man in America, Extinct, J. H. Cotter, 243; of Ireland, C. B. Moffat, 292
- Man: and the Machine Age, Prof. A. Meusel (*Review*), 45; and his Work, Museum Study of, de La Valette, 1108
- Manchester University: Prof. F. Wood Jones appointed professor of anatomy in, 15; A. D. Ritchie appointed Sir Samuel Hall professor of philosophy and public administration, Prof. P. M. S. Blackett, Langworthy professor of physics, H. Davenport, P. Du Val and W. W. Sawyer, assistant lecturers in mathematics, G. D. Rochester, assistant lecturer in physics, D. G. Evans, assistant lecturer in chemistry, E. L. Patterson, assistant lecturer in anatomy and Miss Margaret I. Williams assistant lecturer in applied physiology, 207; Scientists' Peace Association, Address to, by Prof. H. Levy, 1055
- Marconi: the Man and his Wireless, O. E. Dunlap, jun. (*Review*), 260; Guglielmo, and the Development of Radio Communication, Sir Ambrose Fleming, 963; School of Wireless Communication, 1005
- Marine: Engineering, Progress of, S. J. Pigott, 539; Engineering and, Exhibition at Olympia, 553; Eggs, Action of certain Substituted Phenols on, in relation to their Dissociation, A. Tyler and N. H. Horowitz, 779
- Marketing, Electricity and, F. H. Slade, 311

- Mud: Fluid for Pressure Drilling Conditions, Dr. J. T. Evans, 202; Drilling, P. Evans and A. Reid, 1025
- Museum Collections, Improvement of, Dr. W. E. Swinton, 784
- Museums: Association, Annual Conference of the, Presidential Address by Alderman O. Squire, 184; Empire grants committee for, 469; and the People, 784
- Musket's Discovery of Blackband Ironstone [1837], 80
- Music: Physics of (*Review*), 947; and Sound, L. S. Lloyd (*Review*), 947; Science and, Sir James Jeans (*Review*), 947
- Myxidiacid Crustaceans, New Species of, Prof. W. M. Tattersall, 775
- Mysticism, Theory and Art of, Prof. R. Mukerjee (*Review*), 636
- Mytilus, Miss Kathleen M. White (*Review*), 633
- Myxobacteria—The, Cellulose-degrading Agents, Mme. H. Krzemleniewska and S. Krzemleniewski, 187

- Na⁺⁺⁺ Ion, Decomposition of the Ground Term of, Absorption spectra evidence of the, due to Crystalline Fields, Prof. D. M. Bose; Dr. W. G. Penney and G. J. Kynch, 109
- National: Physical Laboratory, Inspection by the General Board, 86; Institute for Research in Dairying, Dr. G. W. Scott Blair appointed head of the chemistry department of the, 61; Museums of Natural History, F. Chapman, 278; Health, Milk Supply and, 295; Fitness: the First Steps (*Review*), 561; Research Council, gift to the, by the John and Mary R. Markle Foundation of New York, 583; Institute of Agricultural Botany, Value of System of substation of the, Capt. D. M. Wills, 843
- Nation's Intelligence, The, J. L. Gray (*Review*), 528
- Nature: the Mechanism of, being a Simple Approach to Modern Views on the structure of Matter and Radiation, Prof. E. N. da C. Andrade. Revised and enlarged edition (*Review*), 260; Photography: Thirty years of, a Personal Record of two observers, Seton Gordon (*Review*), 802
- Natural History: Outlook, Prof. J. Ritchie, 417; in the Schools, 431
- Nauka Polaka. Tom (Vol.) 22 (*Review*), 133
- Naval: Architects, Institution of, award of the Sir William White postgraduate scholarship to A. M. Baxter, 422; Architecture and Engineering, 597; Architects, Institution of, award of scholarships to S. F. Rice, A. Silberblatt and P. Martin, 722
- Navy: Engineering Progress in the, Prof. C. J. Hawkes, 1024; Meteorology in the, 1057
- Neanderthal Tooth, A Lost, 961
- Nebulae: in Places, A New Cluster of, F. Zwicky, 293; Red Shifts and the Distribution of the, Dr. E. Hubble, 649
- Nematodes: Parasitic in Animals, Dr. G. Lepage (*Review*), 526; Physiology of, D. G. Davey, 645; of Horses and Sheep, Control of, I. W. Parnell, 686
- Neodymium Acetylacetonate, Influence of the Solvent on the Absorption Spectra of, Mlle. Milka Radotichitch, 81; Atomic Weight of, Honigshmid, 1104
- Neural Induction: by Fragments of Dead Tissues and Organs of Amphibia and Mammalia in the Ectoderm of the Anuran Gastrula, Prof. G. A. Schmidt, 199; by Plant Tissues in the Ectoderm of the Gastrula of *Triton taeniatus*, M. N. Ragosina, 199
- Neutrino: Theory of Light, The, V. Fock, 113; Shower, β -Decay as due to a, N. S. Nagendra Nath, 278; Theory of Light in Three Dimensions, A. Sokolow, 810
- Neutron: Beams, Polarized, A Method of obtaining, Dr. H. v. Halban, jun., 425; Levels, Resonance, of Silver, Rhodium and Bromine Nuclei, Spacing of the, C. Y. Chao and T. H. Wang, 788
- Neutrons: Production of Mutations by, Mary Nagai and G. L. Loeber, 111; from Lead, Expulsion of, by Cosmic Rays, B. Arakatsu, K. Kimura and Y. Uemura, 277; inside Magnetized Iron, The Magnetic Field acting upon, Dr. O. R. Frisch, Dr. H. von Halban, jun. and Dr. J. Koch, 360; Slow, in Light Elements, Capture of, Dr. O. R. Frisch, Dr. H. von Halban, jun. and Dr. J. Koch, 895
- Newcomen Society, Annual General Meeting; Eng.-Capt. E. O. Smith elected president, 964
- Newfoundland Amphipoda and Decapod Larvae, Miss Nancy Frost, 898
- New York Botanical Garden, Journal of the, Papers by Dr. J. K. Small, 274
- New Zealand: Fish Oils, F. B. Shorland, 223; Australia and, Science in, 231
- Nickel: Wire, Magnetic quality of, as influenced by the Surface, Dr. T. F. Wall, 238; Cementation of, by Beryllium, J. Laisus, 251
- Nicotinic Acid and the Pellagra-Preventing Vitamin, Dr. L. Harris, 1070
- Nigeria, Indirect Rule in, R. S. Rattray (*Review*), 826
- Nigerian Tribe: Law and Authority in a, a Study in, Indirect Rule, Dr. O. K. Meek (*Review*), 826
- Night Sky: in August, 190; in September, 358; in October, 581; in November, 766; in December, 929
- Nile, Dry-crossing of the, E. J. Wayland, 811
- Nitric Oxide: and Alkyl Ethers, Prof. M. W. Travers, 107; NO, Magnetic Rotatory Power of Compressed and of Liquefied, H. Bizette and B. Tsai, 208; Acid, Reduction of, to Hydroxylamine by the Higher Plants, M. Lemoigne, P. Monguillon and R. Desvieux, 293
- Nitrogen: Organic Chemistry of, Prof. N. V. Sidgwick. New edition, revised and rewritten by T. W. J. Taylor and Dr. W. Baker (*Review*), 4; Excretion of, by Leguminous Plants, Prof. P. W. Wilson, 154; Heavy, Prof. H. C. Urey, 498; Isotope, Concentration of, Prof. H. C. Urey, M. Fox, J. R. Huffman and H. G. Thode, 512; Excretion of, by Leguminous Plants, Prof. A. I. Virtanen; Dr. G. Bond, 683; Spectrum of, and Atmospheric Pressure at High Altitudes, R. Bernard, 930; Fixation, Symbiotic Mechanism of, P. W. Wilson and E. B. Fred (2), 943
- Nobel: prize for medicine, award of the, to Prof. A. von Szent-Györgyi, 798; prizes: award for physics to Dr. C. J. Davison and Prof. G. P. Thomson and for chemistry to Prof. W. N. Haworth and Prof. P. Karrer, 882
- Nocht, Bernard, Medal, awards of the, 1009
- Noise: Meters, Performance of, in terms of the Primary Standard, B. G. Churchoer and A. J. King, 331; and the Nation, Dr. G. W. C. Kaye, 408; 446; 490; Dr. A. H. Davis (*Review*), 637
- North: East Coast Institution of Engineers and Ship-builders, awards made to H. Hunter, H. E. L. Martin and R. A. Lyall, 500; Pole Station, 765; Sea and Baltic, Parasitic Copepods of the, G. M. van Oordele Lint and J. H. Schuurmans, 686; West Passage, New, 802; Polar Station, The Soviet, 1040
- Northumbrian Art, Scandinavian Influence on, T. D. Kendrick, 1090
- Norway, Medical Literature of [1837], 598
- Nova Herculis, Spectrum of, D. B. McLaughlin, 593
- Nuclear Particles, Interaction of, Dr. N. Kemmer, 192
- Nuffield College, Oxford, 799
- Nutrition: and Dietetics (*Review*), 829; and Health, 874; Final Report of the Mixed Committee of the League of Nations on the relation of Nutrition to Health, Agriculture and Economic Policy, 874
- Nutritional Science: Social and Political Application of, 305; Social Aspects of, 865
- O₂+ Bands, Visible, Rotational Analysis of the, T. E. Nevin, 1101
- O Σ 79, Orbit of, L. T. S. Syme, 688
- Oakhurst Shelter, George, Archaeology of the, A. J. H. Goodwin, and others, 167; A. J. H. Goodwin (8), 334; (6 and 7), 656
- Occipital Perforation in the Anthropoids, Prognathism, Cranial Capacity and Area of the, E. Pittard and H. A. Seylan, 757
- Octanes, A Maman, 656
- Oestradiol Monobenzoate, Inhibition by, Response of the Pigeon Crop Gland to Prolactin: Drs. S. J. Folley and P. White, 505
- Oestrous Reactions, including Mating, produced by Triphenyl Ethylene, J. M. Robson and Dr. A. Schenberg, 196
- Official Statistics of the United Kingdom, Guide to Current, for 1936, 1057
- Ohio-Mississippi Floods of 1937, The, R. W. Davenport, 666
- O—H Raman Frequency in Inorganic Acids, The, Dr. C. S. Venkateswaran, 151
- Oil: Drops, Collision of Two, and the Stability of a Non-spherical Oil-drop, Yoshio Ishida, 70; Wall Coating, a New Type of, Threaded Connection for, W. M. Frame, 117; from Coal, Commercial Production of, Lord McGowan, 143; Drops, Two, Collision of, and the Stability of a Non-spherical Oil Drop, Y. Ishida, 158; Transport in the Middle East, Col. H. B. Medlicott, 312; Industry, Education and Training for the, Prof. A. W. Nash, 459; Engine, Two-stroke Cycle, Development of the, W. S. Burn, 597; Industry, Indian, R. Evans, 765; Origin of, Dr. P. D. Wraak, 857

- Oils from Irish-grown Plants, 843
 Oldoway-Expedition 1918, *Wissenschaftliche Ergebnisse der Herausgegeben von Prof. H. Reck. Neue Folge, Heft 4 (Review)*, 6
 Omnibus Workers, Digestive Troubles Among, 269
Ophelia cluthensis McGuire, Anatomy of, R. S. Brown, 292
 Optum, Indian, Chemistry of, Dr. H. B. Dunncliff, 92
 Optical: Contact, Propagation of, Dr. J. Weir French, 321; Sensitizing of Silver Halides by Dyes, Mechanism of, Dr. S. E. Sheppard, Dr. R. H. Lambert and R. D. Walker, 1096
 Optics: Experimental (*Review*), 216; Introduction to, Dr. G. B. Deodhar (*Review*), 216
 Oracles, The S.S., 498
 Organo: Syntheses, L. F. Fleaser, editor-in-chief. Vol. 17 (*Review*), 49; Evolution, Processes of, 379; Oxides, Dissociable, C. Dufraisse and J. Houppilart, 1027
 Osiris, Marriage of, G. D. Hornblower, 854
 Osteopathy?, What is, Drs. C. Hill and H. A. Clegg (*Review*), 788
 Overheads, Control of, 354
 Owl, Little, Food of the, 1103
 Oxford: Farming Conference, Forthcoming, 928; University: Dr. A. D. Gardner appointed reader in bacteriology; conferment of title of professor on Dr. A. D. Gardner; Dr. A. H. T. Robb-Smith appointed assistant director of pathology at the Nuffield Institute; G. L. Camm awarded the senior mathematical scholarship; Dr. H. M. Sinclair elected an official fellow and tutor in physiology at Magdalen College; J. F. Hope Simpson elected a senior scholar in botany and J. A. Moy-Thomas re-elected a lecturer in zoology; M. Abercrombie elected a junior research fellow at Queen's College and E. P. Abraham to a readership; R. Campbell Thompson elected Shillito reader in Assyriology, 38; E. H. Leach appointed William Hulme lecturer in physiology at Brasenose College; M. S. Wills awarded the Scott scholarship in physics; F. G. W. Knowles elected to the Naples biological scholarship, and F. Fulton awarded the Radcliffe scholarship in pharmacology, 166; Prof. J. H. Burn appointed professor of pharmacology, 227; R. H. Hodgkin elected provost of Queen's College, 676; further gifts from Lord Nuffield, 879; Dr. G. M. B. Dobson elected an official fellow of Merton College and Prof. R. Campbell Thompson a professorial fellow; Dr. S. Flexner and Dr. J. A. Gunn elected supernumerary fellows of Balliol College, Dr. J. H. Burn a professorial fellow and J. St. L. Philpot a senior research fellow; Dr. A. A. Balke appointed a senior research fellow of Brasenose College, 694; Lord Nuffield's new gifts to, 697; Nuffield College, 799; conferment of the degree of M.A. on Lord Nuffield; Dr. L. J. Witts appointed Nuffield professor of clinical medicine; award of the Scott scholarship for research in physics to J. G. Daunt; gift from the Rockefeller Foundation, 819; conferment of an honorary doctorate on Dr. R. R. Marett; K. A. H. Murray elected fellow and bursar of Lincoln College, 862; conferment of an honorary doctorate on Dr. R. R. Marett, 923; Dr. J. V. Harrison elected lecturer and demonstrator in geology; students in receipt of financial assistance, 1026; Early Astronomical Instruments, Dr. R. T. Gunther, 1089
 Oxiana, The Road to, R. Byron (*Review*), 788
 Oxidation: in the Living Cell, Distinguishing the Zones of, by the Method of Cobalt Salts, P. Joyet-Lavergne, 125; Catalyst, A New, J. G. Dewan and D. E. Green, 1097
 Oxide Film Formation on Metals, Polarimetric studies of, A. B. Winterbottom, 364
 Oxides: in the Extreme Infra-red, Transmission of some, M. Parodi, 208; formed on Iron, Electron Diffraction Studies of, T. Jimbri, 278
 Oxonium Compounds, Raman Spectra of, Dr. G. Briegleb and W. Lauppi, 236
 Oxyacids, Polarimetric Titration of the, F. Gonick, 167

 Porcellanids and Pinnotherids from Tropical North American Waters, S. A. Glassel, 33
 Porous Structure, Investigation of, G. Graue and N. Riehl, 327
 Porphyrinuria, Congenital: Living Animal Cases of, P. J. Fourie and Dr. O. Rimington, 68; Porphyrins of the I and III Series in, Dr. O. Rimington, 105
 Portolan Charts, The Problem of the (Review), 662
 Positron and Electron Pairs, Production of, by bombardment of Mercury with β -Particles of Low Energy, Dr. F. C. Champion and A. Barber, 105
 Postular Fever and Purpura Fever of the Rocky Mountains, Crossed immunity between the, G. Blane and M. Baltazard, 905
 Potassium: Isotopes of, J. H. Yoe and R. T. Hall, 34; Resonance Lines of, Intensity Ratios of the Hyperfine Structure Components of the, Dr. D. A. Jackson and H. Kuhn, 276; and Paralysis, Aitken, Allott, Castle-den and Walker, 367
 Potato: The, in its Early Home and Its Introduction into Europe, Dr. R. N. Salaman (Masters lectures), 169; Vitamin C in the, J. B. H. Ijdo, 977; Synonym Committee, Report for 1936, 1008; Slopes, Standardization of, for Bacteriological Tests, D. Ward Cutler and Miss Mabel Dunkley, 1015; Flowers and Dissemination of Potato Viruses, Dr. G. Cockerham, 1100
 Pottery in the Palaeolithic period, J. P. T. Burchell, 900
 Prediction: Some Cases of, A Study, Dame Edith Lytton (Review), 1078
 Pregnancy, Nutritional Requirements of, Sir Robert McCarrison; Dame Louise Mallory, 188
 Prehistoric: Archaeology, Boucher de Perthes and the Foundations of, L. Aufrère, 261; Finds at Glasgow, 540
 Primates from the Miocene of Lower Austria, Two new remains of, K. Ehrenberg, 125
 Privilege, Registration and, 660
 Probability, Theory of, International Conference on the, Prof. E. L. Dodd and Dr. J. Neyman, 938
 Professional Civil Servants, Institution of, Eighteenth annual report for 1936, 590
 Progesterone alone and in combination with the other Sexual Hormones, Effects on Ovariectomized Rats of, Dr. V. Korenchevsky and K. Hall, 154
 Prohibition and Cirrhosis of the Liver, Dr. C. C. Weeks, 20
 Prolactin: Response of the Pigeon Crop Gland to, inhibition by Estradiol Monobenzoate, Drs. S. J. Folley and P. White, 505
 Proliferation-promoting Substances from Cells injured by Ultra-violet Radiation, G. S. Sperti, Prof. J. R. Loof-bourow and Sister Cecilia Marie Dwyer, 643
 Prontosil in Puerperal Infections, G. F. Gibberd and others, 284
 Prosperity Beckons: Dawn of the Alcohol Era, Dr. W. J. Hale (Review), 637; Protein, Structure of, Prof. C. R. Harrington and others, 491
 Proteins: Patterns of, Dr. Dorothy M. Wrinch, 244; and Metaphosphoric Acid, Reaction between, Dr. H. Hermann and G. Perlmann, 907; 'Fibrous' and 'Globular', Relation between, Dr. W. T. Astbury, 968
 Proton tracks, Measurement of the length of, by the Photographic Method, Dr. Mariette Blau and Dr. Hertha Wambacher, 252
 Protoplasm, Structure of, Dr. A. R. Moore, 367
 Protoplasmic Streaming, Action of Auxin on, Prof. K. V. Thimann and Miss Beatrice M. Sweeney, 907
 Protozoa, Effects of Salts on Emergence from the Cyst in, K. V. Thimann and A. J. Haagen-Smit, 645
 Prussian Academy of Sciences, Philosophical and Historical Section, Prof. F. W. Thomas elected a corresponding fellow of the, 55
 Psittacosis, Laboratory Diagnosis of, 32
 Psychology: Medical, Modern Discoveries in, Dr. C. Allen (Review), 343; in Autobiography, A History of, Vol. 3, J. R. Angell and others (Review), 830; Down the Ages, Prof. C. Spearman. 2 Vols. (Review), 909; Science in, Prof. F. Aveling (Review), 909
 Psychopathology, A Survey of (Review), 343
 Public Health in Great Britain, Sir Arthur MacNalty, 927
 Pultusk: Meteorite, Number of Fragments of the, Dr. E. Stens, 113; Stones, Meteorites: and the Spelling of "Widmanstätten Figures", Prof. F. A. Paneth, 504; Dr. L. J. Spencer, 589; Prof. F. A. Paneth, 909
 Purple, Visual, Absorption Curve for, and the Electrical Response of the Frog's Eye, Prof. R. Granit, 972
 Pygmy Hosts, Revisiting My, Dr. P. Schabetska. Translated by G. Griffin (Review), 445
 Pyrimidine and Thiazole Intermediates as Substitutes for Vitamin B₁, W. J. Robbins, Mary A. Bartley, A. G. Hogan and L. R. Richardson, 779
 'Pyrotex', a Fire-resisting Cable, 887
 Pyrroles Derived from Acetylacetone, S. J. Haxlewood, G. K. Hughes, F. Lons and others, 695
 Pyruvic Acid Dehydrogenation, Vitamin B₁, and Cocarboxylase, F. L. Lipmann, 25
 Quantiques, theories, Introduction mathématique aux, Prof. G. Julia (Review), 950
 Quantitative Inheritance, Relation of Gene to Character in, E. W. Sinnott, 83; Analysis: a Theoretical approach, Prof. W. Riemann, III and Dr. J. D. Neume (Review), 914
 Quantity Surveying for Builders, W. L. Evershed. Fourth edition (Review), 7
 Quantum: Statistics, Joule-Thomson Effect and, Dr. D. S. Kothari and B. N. Srivastava, 970; Low, Ionizing Radiations of, Emitted Spontaneously by the Ordinary Metals, G. Rebol and J. Rebol, 1073
 Quaternary Deposits in the Traun Valley Region above Gmunden, Geological Analysis of the, G. Göttinger, 41
 Quaternions, Functions of, V. C. A. Ferraro, 1111
 Queen Mary: and the Bodleian Extension, 15; College Jubilee Celebration, 1003
 Quinault Indians, Washington, U.S.A., 201

- 'Racemic Acid', Use of the name, Prof. A. Findlay, 22
Races et Racieme, 458
 Racial: Doctrine and Social Evolution, 945; Evolution and Archaeology, Prof. H. J. Fleure (Huxley memorial lecture), 945, 981
 Radcliffe Observatory, Pretoria, 841
 Radiant Energy, Measurement of. Edited by W. E. Forsythe; Dr. N. R. Campbell (*Review*), 828
 Radio: Communication: Fading in, Reduction of, 76; Phase Fading in Long-distance, Control of, Drs. A. L. Green and O. O. Pulley, 76; Exhibition, The, at Olympia, 474; Waves in the Atmosphere, Reflection of, R. A. Watson-Watt, A. F. Wilkins and E. G. Bowen, 512; Research, Foundation by J. W. O. Hamilton of prizes for, 641; Findings, Bright Solar Eruptions and, in 1935-36, H. W. Newton and H. J. Barton, 688; -phosphorus in Tissues of Growing Chicks, Deposition of, S. F. Cook, K. G. Scott and P. Abelson, 944; -sodium in Normal Human Subjects, Rates of Absorption of, J. G. Hamilton, 944; Communication, Guglielmo Marconi and the Development of, Sir Ambrose Fleming, 983
 Radioactive: Substances in the body of Rats, Retention of, and the Lethal Dose, Dr. F. Běhounek and F. V. Novák, 106; Measurements, Utilization of Photoelements with semi-conducting layer for, P. Bonét-Maurry, 308; Elements, Artificial, Production of, A. Eckardt, 649
 Radiology: British Institute of, Annual Congress and Exhibition, 1069
 Radish and Turnip, Crosses between, L. E. Morris and R. H. Rishharia, 285
 Radium: Therapy, Research on, 313; Committee, Report for 1936, 333; Therapy, Science in, 1108
 Rain, Observations on [1837], 819
 Rainfall, British, 1936 (*Review*), 873
 Rainstorms, Run-off after, J. R. Daymond, 470
 Raman Spectra: of Oxonium Compounds, Dr. G. Briegleb and W. Lampe, 236; of Deuteroethylenes, Prof. M. de Hamptinne, J. Jungers and Dr. J. Delfosse, 323; of the Two Forms of Phosphorus Pentachloride, H. Moureu, M. Mogat and G. Wétroff, 598; of Acrylic Acid and of Methyl Methacrylate, both monomer and polymerized, D. Monnier, B. Suzs and E. Briner, 737
 Ramsay Memorial Fellowships, award of, 1008
 Random Observations, Tests for, W. O. Kermack and A. G. McKendrick, 369
 Rare: Earths, Separation of the, Fischer, Dietz and Jühermann, 74; Earth Sulphates, Magnetic Anisotropy of, and the Asymmetry of their Crystalline Fields, Prof. K. S. Krishnan and A. Mookherji, 549
 Rathmullen District, Co. Donegal, Structure of the, W. J. McCallen, 167
 Rats: Adrenals of Normal and of Castrated Male, Histological Changes produced by Castration and by Sex Hormones in the, K. Hall and Dr. V. Korenshevak, 318; Liver Extract and Hemoglobin in, A. L. Bacharach and H. E. Glynn, 896
 Raw Materials, Distribution of, Prof. I. Högbom, 801
 Reaction: Heat of, The Sign and Symbol of, Dr. H. J. S. Sand, 809; Kinetics, Discussion on, 902
 Reading University: Dr. G. W. Scott Blair appointed head of the Dairy Chemistry Department of the National Institute for Research in Dairying, 654; Sir Samuel Hoare elected chancellor, 694
 Reality in Physics, Problem of, Prof. R. Ortqvist, 313
 Rebels: Faithful, a Study in Jewish Speculative Thought, Dr. I. Levine (*Review*), 218
 Recollections of My Life, Santiago Ramón y Cajal, translated by Prof. E. H. Craigie, with the assistance of Prof. J. Cano (*Review*), 617
 Red: Compounds formed by Floric Acid and Creatinine in the Presence of Sodium Hydroxide, A. Bolliger, 519; Rocks, Origin of the, Dr. R. L. Sherlock and others, 554
 Refraction Effect, a Double, in Certain Fatty Materials, L. Bellingham, 70
 Registration: and Privilege, 660; and Population Trends, Dr. R. R. Kucynski, 986
 Relativity: Double Stars and, Prof. T. Levi-Civita, 470; The Philosophy of, Prof. A. P. Ushenko (*Review*), 636; Theory of Protons and Electrons, Sir Arthur Eddington (*Review*), 742
 Renaissance française, award of the Paul Appel prize and gold medal of the, to the French League against Cancer, 104
 Rengma Nagas, The, J. P. Mills (*Review*), 564
 Rensselaer Polytechnic Institute, Work of the, 419
 Repton School Science Society, 18
 Research and Industry, 437
 Reservoir Dams, Fault-movements and the Safety of, G. D. Louderback, 160
 Resins, Synthetic, Examination of, by X-Rays, N. J. L. Megson and W. A. Wood, 642
 Resorcinol, A New Form of, A. R. Ubbelohde and Dr. J. M. Robertson, 239
 Respiration, Artificial, Production of, by Rhythmic Stimulation of the Phrenic Nerves, Prof. R. A. Ward, 849
 Retina, Structure of the, and the Role of its Visual Purple, Dr. R. J. Lythgoe (Thomas Young oration), 1045
 Rhodes-Livingstone Memorial, Proposed, 57
 Rhodesia, Antiquity of Man in, A. L. Armstrong, Rev. N. Jones and H. B. Maufe, 469
 Rhododendron: A Pest of the, G. F. Wilson, 202; Hybrids of the, F. C. Puddle, 813
 Rice, Genetics of, B. S. Kadam and others, 1068
 Rickets: Experimental, Influence of Iodine and of Some Inorganic and Organic Iodine Compounds on the Bone Lesions of, R. Lecoq, 334; Experimental, of Rats, Protective Effect against of a Single Massive Dose of Vitamin D, Dr. H. Rotter, 973
 Riga, Institution of an Institute for Anatomy, Physiology and Hygiene at, 21
 Rigi Railway, Electrification of the, 355
 Ritchie, F. R. S., Prof. William, [1837], 476
 River Flow Around Bends, Dr. B. Cunningham, 728; Records, Capt. W. N. McClean. Series A: River Garry. Sheet No. 1; Sheet B: River Moriston. Sheet No. 1, Series C: River Ness. Sheets 1-14 (*Review*), 872
 Rivers, R. K. Grosswell, 496
 Riveted Joints in Boilers, Chemical Intercrystalline Fracture of, Dr. S. F. Dorey, 597
 Road: Engineering, Principles of, Prof. H. J. Collins and C. A. Hart (*Review*), 441; Rules of the, Enforcement of the, Dr. H. C. Dickinson, 580; Design and Road Safety, F. C. Cook, 650; Research: Board, Report of the, for year ended 31st March, 1936, 983; Progress in, 983
 Roads, Coloured, C. W. Manlove, 1091
 Roaring Sands of the Kalahari Desert, A. D. Lewis, 285
 Rock Magmas and their Products, Prof. C. E. Tilley (*Review*), 913
 Rockefeller: Travelling Fellowships in Medicine, award of, 61; Institute for Medical Research, Hospital of the, retirement of Dr. R. Cole and appointment of Dr. T. M. Rivers as director, 104; Foundation, Activities of the, in 1936, R. Foodick, 500
 Rocks and Minerals, Chemical Analysis of, R. C. Wells, 202
 Roman: Site at Wroxeter, Excavations on the, 352; Britain: Local Government in, 394; Recent Excavations in, 654; Pottery from Ewell, Surrey, 924
 Röntgenstrahlen, Materialprüfung mit, Prof. R. Glocker. Zweite auflage (*Review*), 914
 Ropes, Winding, Fibre Cores in, 818
 Ross Institute, Activities of the, 581
 Royal: Aero Club, Miss Jean Batten awarded the gold medal of the, 844; Aeronautical Society, award of medals and prizes, 1094; Agricultural Society, ninety-seventh volume, 357; Asiatic Society, award of universities essay prizes to D. P. Costello and J. Bowman, 967; Cancer Hospital, gift to the, by A. Chester Beatty, 844; College of Physicians of London, award of the Baly medal to Prof. E. L. Kennaway, 232;

- presentation of the Baly medal to Prof. E. L. Kennaway, 722; College of Surgeons of England, opening of the Bernhard Baron laboratories, 1045; Cornwall Polytechnic Society, Annual Report, 59; Geographical Society, [1837], 1026; Institute of British Architecture, Sir William Bragg elected an honorary associate of the, 21; of International Affairs, Prof. A. G. B. Fisher appointed professor of international economics, 842; Meteorological Society, award of the Howard prize to Cadet Ralph Wills, 21; award of the Symons gold medal to Dr. G. M. B. Dobson, 929; Prof. A. S. Spillans elected a foreign member of the, 1058; Navy, The Engineering Branch of the, [1836], 123; Observatory, Greenwich, Dr. R. d'E. Atkinson appointed chief assistant in the, 457; Society: J. D. G. Davies appointed assistant secretary, 460; award of Royal medals to Prof. N. V. Sidgwick and Prof. A. H. R. Buller, Copley medal to Sir Henry Dale, Davy medal to Prof. H. Fischer, Buchanan medal to Gen. F. F. Russell, Sylvester medal to Prof. A. E. H. Love and Hughes medal to Prof. E. O. Lawrence; Sir William Bragg recommended for re-election as president, 840; new barometer [1837], 862; Anniversary of the, [1837], 941; Anniversary meeting and presentation of medals, 979; Society of Arts, Annual Report, 1008; of Canada, annual meeting; award of the Flavelle medal to Dr. F. D. Adams, the Lorne Pierce medal to Prof. S. Leacock and the Tyrrell medal to A. Fauteux; Prof. A. G. Huntsman elected president for 1937-38, 287; of Edinburgh: election as honorary fellows of Dr. W. T. Calman, J. L. Baird, Prof. O. U. A. Kappers, Prof. M. T. Bogert and Prof. Max Planck, 61; election of officers, 766; of Tropical Medicine and Hygiene, award of the Chalmers medal to Prof. R. M. Gordon, 98; Veterinary College and Hospital, opening of new buildings of the, 884
- Rubber, Diffusion Process in, Nature of the, R. M. Barrer, 106
- Rubidium-Cesium Alloys, Diagram of Solidification and Electrical Conductivity of the, E. Rinak, 518
- Rural Hygiene, Far Eastern Conference on, 353
- Russia: Medical Practitioners m., [1837], 39; Medical Schools in, [1837], 81; Hospitals in, [1837], 207

 G. Fitzgibbon and Dr. M. A. Hogan, 73
 Sex: Chromosomes, Human, Dr. P. C. Koller, 429;
 Ratio, The, Prof. F. A. E. Crew, 449; Prof. F. A. E.
 Crew and others, 958; Behaviour, Effect upon, of a
 Diet Deficient in Vitamin E, Dr. B. P. Wicmer and
 A. L. Bacharach, 972
 Sexual Periodicity, Dr. F. H. A. Marshall, 284
 Sheep: Diseases, Cobalt, and, J. B. E. Patterson, 363;
 Cobalt Chloride Treatment of, J. K. Dixon, 898
 Sheffield University, J. W. Watson appointed assistant
 lecturer in geography, G. Forbes lecturer in forensic
 medicine, J. M. Kennedy lecturer in infectious
 diseases and G. A. de Belin assistant lecturer and
 research assistant in the department of metallurgy,
 207; gift by the City Council for the Extension
 Fund; E. T. Goodwin and T. D. H. Baber appointed
 assistant lecturers in mathematics and Dr. Helen
 Mellenby part-time demonstrator for medical and
 dental students; resignation of J. W. Frame, J.
 Jenkins and Dr. E. S. Duthie, 735; twenty-first
 anniversary of the Society of Glass Technology; new
 buildings for the department of glass technology,
 884; H. J. Barrie appointed demonstrator in
 pathology and R. B. M. Jenkins assistant lecturer in
 civil engineering, 904
 "Shiva's Temple", Arizona, Investigation of, 537; Dr. H.
 Anthony, 613
 Shoreham Harbour, Excessive Marine Growth in, 966
 Short: Waves in Physics, Biology and Medicine, Inter-
 national Congress for, Vienna, Dr. J. B. Bateman, 372
 Short-Mayo Composite Aircraft, 539
 Show Cases, Illuminated, 312
 Showers, Production of, by Heavy Particles, Dr. L.
 Landau and G. Rumer, 682
 Silica Dusts, Solubility of, Dr. E. J. King, 320
 Silicon in Steels, Determination of, G. Charpy, 820
 Silkworms, Diet of, [1837], 207
 Silver: Nitride, Slow Thermal Dissociation of, Ultra-
 Violet Emission Spectrum of the, R. Audubert, 518;
 Halides, Optical Sensitizing of, by Dyes, Mechanism
 of, Dr. S. E. Sheppard, Dr. R. H. Lambert, and R. D.
 Walker, 1096
Sinanthropus: pekinensis, Reconstruction of the Entire
 Skull of an Adult Female Individual of, Prof. F.
 Weidenreich, 1010; VI, Prof. F. Weidenreich, 1067
Sirius, The Iron Ship, [1837], 556
 Siwa, Oasis of, Egyptian Libya, Zoological Expedition to
 the, J. Omer-Cooper, 919
 Skatole as a Root-forming Substance, L. G. G. Warne and
 A. A. Jackson, 26
 Sladen, Percy, Expedition to Lake Titicaca, H. C. Gibson,
 877
 Sleep and Narcosis, Promotion of, by Dyes, H. Konsett, 821
 Smith, Theobald, award in medical science, Dr. R. D.
 Evans presented with the, 460
 Smithsonian Institution, Field Work of the, in 1936, 356;
 List of the Publications of the, Helen Monro, 616
 Smoke Abatement Society: National, Annual Conference
 at Leeds, Dr. A. L. Roberts, 691
 Snake Venoms, The European (Review), 744

 Falling, Physical Investigations on, G. Seligman,
 345; Crystal or Snowflake, Sir George Simpson,
 729; G. Seligman, 730
 Snowflake, Snow Crystal or, Sir George Simpson, 729;
 G. Seligman, 730
 Social: and Economic Problems, International Co-
 operation in, 1; Service, Science in, 253; Theory
 and Discipline, R. Brightman (Review), 481; Research
 Organisation of, 521; Evolution, Racial Doctrine
 and, 945; Contacts of Science, Committee on, election
 of officers, 983; Problem Group? A, Edited by Dr.
 C. P. Blacker (Review), 993; Sciences Lag, Why,
 Dr. J. Mayer, 1021; Service, Science and, Sir
 Richard Gregory, Bt., 1088
 Sociology: The Development of, Prof. F. N. House
 (Review), 481; Medical and Psychological Aspects
 of (Review), 993
 Soft X-Ray Region, Absorption Edges in the, H. W. B.
 Skinner and J. E. Johnston, 732
 Soil: Erosion and its Control, Prof. Q. C. Ayres (Review),
 445; Engineering Properties of, C. A. Hogentogler
 and others (Review), 635; Erosion: The Growth of
 the Desert in Africa and Elsewhere, Sir Daniel Hall,
 886
 Solar: Eclipses: of June 19, 1936, The, Prof. F. J. M.
 Stratton and others, 11; Longest, Observations of
 the, Prof. J. Q. Stewart and T. Stokley, 143; of
 June 8, 1937, Observations of the, Prof. I. Yama-
 moto, 501; Corona, Polarisation of the, K. G.
 Zakharin, 586; Eruptions, Bright, and Radio
 Findings in 1935-36, H. W. Newton and H. J. Barton,
 688; Eclipses, Total, of June 19, 1936, Coronal
 Emission Lines Observed at the, Prof. R. Sekiguti,
 724; Prof. F. J. M. Stratton, 725; Radiation,
 Absorption of, by the Atmosphere in Band A, P.
 Lejay, 943
 Solenoid, Self-inductance of a, Coefficient of, R. Emsalt-
 Pelterie, 1073
 Solids, The Grain-like Structure of, Sir William Bragg,
 954
 Solubility of a Pure Substance, Equation of, Forming a
 Solid Compound with the Solvent, J. Perrou, 477
 Solutes in Vacuolar and Cytoplasmic Saps, Concentration
 of, Dr. E. Phillips and Dr. T. G. Mason, 370
 Solvent Dewaxing, M. Ba Thi, T. G. Hunter, Prof. A. W.
 Nash and others, 1105
 'Sonti' Fermentation, K. Ram Reddi and Dr. V. Subrah-
 manyan, 33
 Sooty Mould Fungi, Ecology of, Miss Lilian Fraser, 1104
 Sorbonne, Paris, retirement of Prof. C. Fabry, 883
 Soufrière de Saint-Vincent, Reality of an Eruption of the,
 in, 1718, A. Lacroix, 656
 Sound: Intensity, Absolute Measurements of, Prof.
 B. N. da C. Andrade and R. O. Parker, 34; Music
 and, L. S. Lloyd (Review), 947; -Films as Diffraction
 Gratings for Visual Fourier Analysis of Sound-waves,
 Dr. D. Brown, 1089
 South: Africa: Native Lands in, A "New Deal", 458;
 Moisture and Farming in, W. R. Thompson (Review),
 698; African: Protectorates, Gen. Hertzog and
 Malcolm MacDonald on the, 99; The Future of the,
 127; Fishes of the Families Sparidae and Dentidae,
 J. L. B. Smith, 334; Native Cattle, H. H. Curson
 and R. W. Thornton, 551; Australia: Mining and
 Geology in, 312; Natural History and Science in,
 Dr. C. T. Madigan, 419; -West Essex Technical
 College, Dr. H. Lowery appointed principal of the,
 803; African Larval Trematodes with Forked Tails,
 F. G. Cawston, 1028
 Soviet: Russia, Birth-rate of, 148; North Polar Station,

International Co-operation in Social and Economic Problems

AT a time when confidence in the League of Nations is being sadly shaken, the progress of the International Labour Organization, as shown by the recently issued annual report, is a welcome reminder of the realities of international co-operation. The emphasis which the tragic events of the last few years has laid upon the necessity of social justice as a condition of peace, both internal and external, has brought the aims and the potentialities of the Organization into stronger relief.

Beyond question the Organization has emerged stronger, and not weaker, from the slump. Its advisory and information services have been increasingly recognized by countries all over the globe. Its activity has been more than sustained, and there was never a time when a wider prospect of constructive work could be discussed; even in membership, the withdrawal of Germany in 1933 has been offset by the entry of the United States, the U.S.S.R. and Egypt.

The outstanding features of the past year have been the success of the American Labour Conference at Santiago, which has stimulated the publication of a series of valuable monographs on economic and social conditions in South America, the Maritime Conference dealing with hours of work at sea and the World Textile Conference convened at Washington at the end of the year.

Despite all political and ideological differences which impede international relations at the present time, the good will necessary for international agreement is still to be found in the social field. The technical aspects of migration problems are once again receiving attention, and a fresh start is being made in dealing with the social problems of the countryside.

What gives especial interest to the annual report prepared by Mr. H. B. Butler, director of the International Labour Office, however, is the admirable survey which he presents of the international situation as a whole. Avoiding the snare of excessive occupation with the details of the progress of the International Labour Organization itself, he gives us a balanced and impartial discussion of many of the national tendencies and policies, upon the integration of which the future of our economic and social order depends. In the present report, for example, he reviews the extent of recovery from the slump, seeks to indicate certain lessons to be learnt and to emphasize some of the main problems and tendencies at the present moment.

To-day there can be no doubt that a large measure of recovery has been accomplished, but there are widespread doubts as to the attainment of any real stability or equilibrium. Moreover, the recovery has been achieved mainly by the

positive action of Governments and peoples, and this in itself affords an excellent reason for learning from experience of a slump to build barriers against the recurrence of similar catastrophes.

The evidence of recovery afforded by charts of production and unemployment is decisive. It is less convincing in statistics of world trade, and freer international trade remains one of the prime necessities if any real confidence about stability or permanence of recovery is to be felt. Only a beginning has been made in stabilizing currencies and in reducing trade barriers, and in the meantime the growth of armaments and the uneconomic activity which it represents constitute a serious threat to such recovery as has been achieved, all the more in a period of rising prosperity. Mr. Butler's survey should leave no one in doubt as to the menace which recent developments in this field present to economic and social progress until a peace system guaranteed by an effective League of Nations has been organized.

It is, however, in his discussion of the lessons of the slump and of current problems and tendencies that Mr. Butler is most suggestive. Against the uncomfortable realization that prosperity does not of itself move along a straight and even course but is inclined to proceed by upward and downward waves, he sets a firm conviction that the experience of the slump has demonstrated that man is capable of exerting a degree of control over his economic destiny. This is the more important because the buffets of economic misfortune are no longer accepted with the same docility as in the past. In fact, the demand for a national economic policy may become as insistent as was the demand for a public health policy fifty years ago.

The experience of the slump has already revolutionized the traditional view of the unemployment problem. It has disposed of the old fetish that there is no such thing as involuntary idleness, and that efforts to provide work or sustenance for the unemployed are an unjustifiable interference with the law of supply and demand. The positive value of State aid to the unemployed has been demonstrated beyond question, independently of its economic value.

Sir Josiah Stamp's recent plea for investigation of population questions finds further support in some of Mr. Butler's comments on population changes in relation to unemployment. The greater difficulty of reabsorbing displaced workers is not due entirely to the greater impact of technical change on the volume of employment; the decline

in the rate of population increase in all Western countries is a much more serious factor, which aggravates the effect of technological unemployment. Moreover, technical changes mean now not merely new vocations for the younger workers or entrants to industry, but also actual displacement of those already at work. Vocational training to an increasing extent involves the training and re-adaptation of the older workers. This situation is the more serious because, while the changing age distribution in population is increasing the supply of older and decreasing that of younger persons, the accelerating tempo of industry is constantly reducing the age of maximum efficiency and consequent demand for older workers.

The difficulty of finding employment for middle-aged workers of all types is enhanced by the natural prejudice in favour of young men and women, even in the newer and growing occupations for which middle-aged men are quite suitable, and one of the gravest dangers at the present time is that the 'hard core' of elderly unemployed will continue to grow, with serious consequences to the whole economy of social services. Fortunately, the experience of the slump provides welcome evidence of the ability of social insurance as an institution to meet the exceptional and unprecedented demands upon it and even to extend its operations. This fact, however, stresses the necessity for close attention to the effect of the changing technique of industry on the character of the insured population and to the biological changes in the composition of almost all Western populations. Only by careful investigation of the problems thus presented can we hope to secure the stability of our social insurance systems under growing pressure.

It is remarkable, in some ways, that the depression has led to increasing recognition of the value of the minimum wage, and that the dogma that the most effective way of combating depression lay in the reduction of wages has largely been refuted. At the same time, it is increasingly recognized that incomes, not wage rates, form the foundation of living standards, and considerable progress has been made in raising the standard of civilization by supplementary methods such as family allowances, educational allowances or social insurance. Equally remarkable is the fact that the problem of leisure has been accentuated, not retarded by the slump. The tendency has been towards shortening the working week and not lengthening it, as in previous slumps. The problem of leisure, whether from the point of view of

holidays with pay or education, forms part of a general demand for a better and wider life which is the present trend of social progress.

Mr. Butler makes pertinent comments upon the importance of monetary policy in its international aspects, but even here he can point to evidence of the beginnings of a new monetary technique, which may assist in dealing with some of these social and economic problems in accordance with the ideal of social practice. Moreover, in the extension of Government intervention in the economic world he sees further possibilities of progress, if only the horizons of thought are widened and not limited to nationalist boundaries. He recognizes that it is almost inevitable for nations to attempt some degree of national self-sufficiency, clearly as he recognizes the dangers and disturbance to progress caused by the voluntary isolation of so large an economic unit as Germany. He reiterates the importance of foresight and planning in connexion with armaments and avoiding another depression,

and the necessity for developing an adequate technique for this purpose in time.

No reader of this report can be in any doubt as to the seriousness of the consequences of certain tendencies in national policies in economic and social affairs at the present time, or to the imperative need for thorough scientific investigation of population and allied questions. Nor does Mr. Butler leave us in any reasonable doubt as to the efficiency of existing international co-operation in social and economic questions. Even the few examples he cites of recent experiments at control within national boundaries indicate how hopeful the future might be if public opinion could be stirred to demand the necessary investigation and co-operate planning. This latest report gives us a most encouraging prospect of the possibilities of social control at the very time when scientific workers have come to consider, on a scale more widely than ever, just what might be done to elaborate an adequate programme and technique.

Offence and Defence in Gas Warfare

Chemicals in War :

a Treatise on Chemical Warfare. By Dr. Augustin M. Prentiss. With Chapters on the Protection of Civil Populations and International Situation, by Major George J. B. Fisher. Pp. xviii + 739. (New York and London : McGraw-Hill Book Co., Inc., 1937.) 45s.

THE author's intention in the publication of this comprehensive work is to present to the public an authentic account of a much misrepresented and misunderstood subject, to give the American point of view on chemical warfare and to trace its development from its beginning in the World War to the present time. He is well qualified to undertake such a task, as he served in the War as assistant to General Fries, who was chief of the Chemical Warfare Service of the American Expeditionary Forces, and he has been on continuous duty in the American Chemical Warfare Service ever since.

Colonel Prentiss describes in full detail all the chemical agents that were used by each of the nations engaged, and also their method of manufacture and their comparative success, and he discusses the probabilities of their future employment as well as post-War developments. He refers to the sensational articles which appear from time to time about some new super-gas, a few hundred

pounds of which, dropped from aeroplanes, could destroy New York. These, he says, are invariably the figments of the imagination of writers who have neither technical nor professional knowledge, and they are found to be, when analysed, without the slightest foundation of fact. But this does not mean that there may not be much more effective chemical agents in the future, though there is little to be gained in finding them while the full possibilities of those already known remain unexploited. For example, an average of only 33 casualties resulted in the War from the use in battle of 1 ton of mustard gas, whereas it has been proved experimentally that there is enough potential poison in this quantity to kill 45 million men !

The evolution of the tactics employed in discharging gas clouds and artillery and trench mortar gas projectiles is traced, and the opinion is expressed that gas troops were more highly developed and more extensively employed by the British (the Special Brigade) than by any other nation. He also confirms the opinion held in Great Britain that the use by the French of prussic acid gas in their shells (of which four millions were filled with the substance) and by the Germans of their Blue Cross shells (of which fourteen millions were filled) were two of the major errors in the gas war. Far too many chemical agents were used in the field, and there were long delays in their

production; and gas was filled into shells designed for high explosive, which, with the fuses supplied, were quite unsuitable for the purpose. In fact, a heavy price was paid for lack of pre-war preparation, and the wonder is now how the amazing results achieved were ever accomplished.

The author has some interesting remarks to offer on the gassing of cities, and he considers that the effects of volatile gases, such as phosgene, can be largely avoided by taking refuge in buildings, closing the windows and doors and seeking the upper floors. Mustard gas sprayed from aeroplanes would be much more effective, and if it reached the target aimed at, it might result in serious non-fatal casualties to all unprotected persons exposed to the vapours for a period of half an hour.

Major Fisher, also of the U.S. Chemical Warfare Service, who has written the chapter on the protection of civilian populations, is of the same opinion. He thinks that the spraying of liquid chemicals from aircraft necessitates flying at altitudes of not more than 300 ft. and the deposit of spray directly on exposed personnel; but that this task would be so difficult that the employment of such liquids in aerial attacks would be limited to the dropping of vesicant-filled containers. "All military experience with chemical warfare,"

he says, "shows that gas may be countered by organized protection. Careful planning and preparation to this end must, therefore, appeal to and elicit the co-operation of every public-spirited citizen." It is interesting to note that the measures he advocates are precisely those recommended in the Air Raid Precautions handbooks published by the British Home Office, namely, the utilization of designated rooms within homes or residential or commercial buildings, and sealing them as gas refuges.

There are very complete chapters on chemical defence, and in summarizing the effectiveness of chemical warfare in the field the author tabulates a great deal of information collected from all available sources to show the increasing use that was made of gas in the War and its relative value to other weapons in casualty production: gas was four to five times more effective. Each casualty required 500 lb. of high explosive or 5,000 rounds of rifle and machine-gun ammunition, whereas a casualty resulted from the firing of every 22½ mustard gas shells.

This volume contains more than seven hundred pages, and is well illustrated. It comprises a very complete and impartial study of chemical warfare in all its phases, and is therefore a valuable book of reference.

C. H. FOULKES.

Organic Chemistry of Nitrogen

The Organic Chemistry of Nitrogen

By Prof. N. V. Sidgwick. New edition, revised and rewritten by T. W. J. Taylor and Dr. Wilson Baker. Pp. xix + 590. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 25s. net.

IT is refreshing to find a book which not only is thoroughly interesting to read on account of the way in which the subject-matter is presented, but is also sufficiently comprehensive to serve, for ordinary purposes, as a reference book for the range of material treated. The second edition of N. V. Sidgwick's "Organic Chemistry of Nitrogen", which has been entirely rewritten by T. W. J. Taylor and Wilson Baker, preserves that balance between interest and comprehensiveness which made the original so valuable. These authors have, in fact, adhered closely to the plan of the first edition in dealing only with the simpler organic compounds of nitrogen, although necessarily the newer book is longer, as it presents much material only discovered since 1910, the date of the first edition. For the most part the actual chapter headings of the two books are the same: the new

edition omits the chapter on derivatives of uric acid, only heterocyclic compounds which contain one nitrogen atom being treated; it omits also the subsection on the simpler alkaloids; it replaces the subsections on amino-acids and on aliphatic diazo-compounds and hydrazoic acid by separate chapters; and it treats all the carbonic acid derivatives together in one instead of two chapters.

Much of fundamental theoretical importance has happened in the twenty-seven years which have elapsed since the publication of the first edition. An old controversy in the chemistry of organic nitrogen centred around the question as to whether nitrogen could exert five valencies. The electronic theory of valency has since provided an answer to this question, leading to the formulation of nitro- and azoxy-compounds, the nitrile and amine oxides, and compounds of the type NR_4 as derivatives of quadri-covalent nitrogen.

In the introduction, Prof. Sidgwick stresses his belief that the conception of resonance is the most important development which structural chemistry has had since its extension to three dimensions by

van't Hoff. Use has been made of this idea throughout the book to explain the remarkable stability of certain compounds (for example, aromatic compounds), the notable modifications often exerted by one group on the properties of another (for example, the amino- on the carbonyl group and vice versa in an amide), and generally the absence of isomers to be expected from the older structural formulæ.

As in the original book, questions of structure are treated very fully, and physical as well as chemical methods of determining configuration are discussed. Here the new edition contains much fresh matter, owing to the development of physical methods. Among these may be mentioned the use of (a) Raman spectra, for example, to prove the presence of traces of $\text{HN}:\text{C}$ in $\text{HC}:\text{N}$, and to elucidate the structure of the isocyanides, the cyanogen halides and the thiocyanate ion; (b) the electron diffraction method, to prove that diazomethane has an open-chain structure; (c) X-ray

analysis, to show that the azide ion is linear; (d) dipole moments, to distinguish between *syn*- and *anti*-*N*-ethers of oximes, to fix the structure of azobenzene as *trans*- and to confirm the structure of the isocyanides; (e) heats of formation of links from atoms, to prove the structure of the cyanogen halides.

The book should be of great value to students: for whereas, under the present system of short intensive courses, it would scarcely be possible for a science degree student to master the whole contents, yet the greater part of it may be said to be useful examination knowledge; whilst to read the whole book cannot but be interesting and stimulating, since it shows how problems are attacked, and indicates, to some extent, further subjects requiring elucidation. To more senior people, no longer students in the technical sense, the new volume will be welcome as an old and valued friend, after long absence returned with added charm and strength.

E. H. I.

Coronation Ceremonial

A History of the English Coronation

By Prof. P. E. Schramm. Translated by Leopold G. Wickham Legg. Pp. xv+283. (Oxford: Clarendon Press; London: Oxford University Press, 1937.) 12s. 6d. net.

NOW that the coronation of His Majesty King George VI is a thing of the past, it is possible to take stock of the more immediate results which have emerged. Among these not the least impressive is the manner in which it has been emphasized on all sides, as never before, that this ceremonial has a living meaning for the peoples of the British Empire. It has been, in fact, from first to last, and not merely on one day and within the Abbey walls, a solemn act of mutual dedication between king and people. In this unprecedented appreciation of the solemnity of the occasion, science has played no small part by the application of its resources to meet the needs of the occasion, especially in methods of record and transmission of news, and more particularly by the manner in which the general public has been enabled to participate in the varied ceremonial and pageantry through the development of wireless telephony and the cinematograph.

This expansion beyond the immediate scene of action in essence breaks no new ground. It follows tradition in incorporating the coronation rite in the life of the people. This has been brought out

by the more serious attempts which have been made to trace the history of the observances marking the inauguration of a king in British history. Among these, Dr. Schramm's account takes its stand in the first rank, if only for its appreciation of distinctive features in a peculiar product of English methods in practical affairs.

In the matter of the English coronation, indeed, Dr. Schramm is something of an enthusiast. His book conveys the impression that not only is it pivotal in the English constitution, but also that its history is a mirror of the relations of king, church and people in domestic affairs, just as, at least in the early stages, it was made a determinant of the status of the English monarch in Continental contacts and policies. In form, Dr. Schramm holds it to be completely an expression of the English character, while in a sense it is its supreme political achievement. His study of the English royal inaugural rite falls into two sections, of which the first is a comparative history of the practices of northern Europe from the time of the earliest records, and the second contains three essays on the theory of the coronation, which deal respectively with the rite of anointing, the electoral element in the acclamation and recognition, and the contractual element in the coronation oath.

Dr. Schramm writes with an authority which is firmly based on a close study of the English coronation *ordines*. His profound knowledge of the medieval mentality, towards questions of a

theologico-legal nature, such as for example investiture, adds weight to his judgment in matters of doubtful interpretation; and when, as on occasion, he differs from generally accepted opinion, his verdict cannot be lightly set aside. His analysis of the development of the rite in relation to the growth of constitutional theory out of current events in the successive periods of English history is both stimulating and suggestive.

The rite, as we know it from textual evidence, is traced by the author to St. Dunstan in the tenth century, its derivation being West Frankish; but the elements of the rite, it is admitted, were of a much more ancient origin. Dr. Schramm

makes the pregnant suggestion that early practice must be viewed in the light of the fact that, in the passing of possession, the Saxons made no distinction between 'public' and 'private'; while the enthronement of the heir is compared with the pagan custom of seating the one who carries on the succession on the burial mound of his predecessor as a clue to the resolution of the apparent opposition between inheritance and election. While Dr. Schramm points out that there is a magical background to the ceremonial throughout, he has barely touched on this aspect. This is the more to be regretted, as he has thereby weakened his treatment of the origins of the rite in what is otherwise an excellent study.

African Pleistocene Mammals

Wissenschaftliche Ergebnisse der Oldoway-Expedition 1913

Herausgegeben von Prof. Dr. H. Reck. Neue Folge, Heft 4. Pp. 142+8 plates. (Berlin: Dietrich Reimer, 1937.) 34 gold marks.

THE fossil remains of mammals found in the Middle Pleistocene freshwater deposits at Oldoway in Tanganyika Territory are interesting because they include several survivors from the Pliocene period, mingled with a typical modern African fauna. Primitive elephants, such as *Dinotherium* and *Mastodon*, and three-toed horses, which became extinct in Europe before the Pleistocene period, lived in east Africa until towards the end of this period, and were associated with numerous mammals which are only varieties of those still existing on the same continent. We therefore welcome another instalment of Dr. H. Reck's valuable volume on the collection of these fossil mammals which he made in 1913, and look forward to the early publication of a similar report on the second collection made in 1931 by Dr. Leakey's expedition, in which Dr. Reck also took part.

The new instalment of the German report begins with an exhaustive description of the remains of antelopes by Dr. Ernst Schwarz. For this work Dr. Schwarz found it necessary to study and compare the skeletons of the existing African antelopes more closely than they had been studied and compared before; and his observations suggest some changes in the generally accepted classification, which he discusses and tabulates. Among the fossils he recognizes only fourteen species, which are very few compared with the number of species now living round Oldoway. He also notes that some

of the fossils belong to species which at present exist only farther north in Africa. With rare exceptions the fossil forms must be regarded as merely varieties of the existing species, but they are sometimes of smaller size with less developed horns. A variety of the brindled gnu is so common that it seems to have lived on the spot in large herds, and a considerable proportion of the remains belong to young individuals.

In the next two chapters Dr. W. O. Dietrich describes some fragmentary remains of pigs and giraffes, among which two teeth and a metacarpal bone of *Sivatherium* are the most interesting. The teeth were at first referred by Schlosser to *Helladotherium*, but the later discoveries by the Leakey expedition suggest that the new determination is more likely to be correct.

In another chapter Dr. A. T. Hopwood describes the remains of horses, among which the distal half of the associated three metatarsals belongs to a three-toed form like *Hipparion*. The teeth, which probably represent the same species, seem to be referable to *Stylohipparion*; this occurs fossil in the Orange Free State. With these fragments have also been found teeth and bones of ordinary one-toed horses, among which the well-preserved lower jaw of an apparently new species of zebra is noteworthy.

In a concluding chapter Dr. Reck himself describes the frontlet with horn-cores of a remarkable antelope, which seems to belong to a new extinct genus. He is to be congratulated on having thus completed the task of making known the Oldoway fossil mammals which he and his colleagues began more than twenty years ago. There now remains only the geological report, which will complete the work. A. S. W.

Annual Reports on the Progress of Chemistry for 1936 Vol. 33. Pp. 512. (London: Chemical Society, 1937.) 10s. 6d.

THE annual reports on the progress of chemistry, published by the Chemical Society, have for long tended to become collections of monographs on selected phases of the process whereby the science is advancing along the parallel paths of experiment and theory. In this way both professional chemists and other readers interested in the progress of the natural sciences can best be presented with an outline sketch of what is in reality a rapidly expanding and frequently changing picture.

The subject-matter is broadly divided into radio-activity and sub-atomic phenomena, general and physical chemistry, inorganic chemistry, crystallography, organic chemistry, biochemistry and analytical chemistry. The method of treatment may be exemplified by quoting the titles of the sections of organic chemistry, as follows: stereochemistry; carbohydrates; natural resins; aromatic compounds; dehydrogenation in the determination of structure; synthesis of polycyclic hydroaromatic compounds; natural products of the sterol group; heterocyclic compounds; alkaloids; vitamin B₁ and thiochrome. Under "Chemical Kinetics", the quantal theory of chemical change, the object of which is to predict the absolute magnitude of the velocity of chemical reactions of all kinetic orders in homogeneous and heterogeneous systems, is discussed. The chapter on atomic weights refers to the importance of establishing an invariable standard for chemical work, a requirement which has arisen from the discovery that oxygen in air is heavier than oxygen combined in water. A summary of recent work on fluorine and its compounds and on the rare earths is given; it is interesting to be reminded that the rare earths as a whole are not particularly rare, being as plentiful in Nature as lead, zinc or cobalt.

Reference is made to a new modification of insulin therapy involving the use of protamine insulinate, and considerable space is devoted to the phenomena of photosynthesis in plants, whilst the new magneto-optic method of chemical analysis is briefly criticized. Since in every case the authors are investigators of acknowledged authority, the volumes of this series are of permanent value as well as of immediate interest.

A. A. E.

An Outline of Malayan Agriculture

Compiled by D. H. Grist. (Malayan Planting Manual, No. 2.) Pp. xiii+388+86 plates. (Kuala Lumpur: Department of Agriculture, 1936.) 3 dollars.

THIS handbook, which has been prepared by the Agricultural Department in Malaya, is an enlarged and completely revised edition of one published some years ago. It supplies information on all aspects of Malayan agriculture.

The first chapters are devoted to a general discussion on agricultural conditions (including land tenure) and agricultural practice throughout the Peninsula. Part 3 of the volume deals in detail with the major crops, which are rubber; coco-nuts, rice,

oil-palms and pineapples. Parts 4 and 5 are devoted to the numerous secondary and minor crops of that region, including the large groups represented by fruits, vegetables and spices. Although some of the crops or plants dealt with, such as the durian, mangosteen and rambutan are typically Malayan or East Indian, most of the others are cultivated generally throughout the tropics. The book should therefore be of interest or value to agriculturalists in other parts of the tropics besides Malaya. In the section on livestock, cattle, pigs, poultry and freshwater fish are dealt with, and in the appendix there are lists of import and export duties, Malayan weights and measures and a full bibliography. A large number of photographs are used to illustrate the text.

The authentic nature of the information and the amount of detail contained in this handbook, combined with the care and thoroughness with which it has obviously been prepared, should place it in the front rank of works on tropical agriculture.

Higher School Revision Mathematics

By L. Croeland. Pp. viii+164+xviii. (London: Macmillan and Co., Ltd., 1937.) 3s. 6d.

THE usefulness of the author's "Revision Mathematics" for the First School Certificate Examination has led to a request from teachers for a similar book dealing with the pure mathematics required by the non-specialist for the Second or Higher Certificate Examination. The present volume has therefore been compiled to supply this demand.

The book provides a large number of exercises arranged in four main groups: algebra, trigonometry, geometry and calculus. Each section is introduced by some fully worked-out questions which are well chosen to illustrate the main points essential for adequate revision. The graphical illustrations are especially clear, and should lead pupils to see that what they sometimes consider to be rather a dull part of the subject, is really very interesting and stimulating. The section on integration, too, deserves special mention for its clarity and completeness. It should certainly help to pilot the pupil through the great sea of the calculus.

The concluding section consists of a very useful set of typical examination papers illustrating the standard required by the various examining authorities.

The book is excellently adapted to its purpose, and may be confidently recommended. We notice a few errors which will no doubt be corrected in a future issue.

Quantity Surveying for Builders:

a Text-Book for Surveyors, Civil Engineers, Builders and Contractors. By Wilfrid L. Evershed. (Directly-Useful Technical Series.) Fourth edition, revised. Pp. xix+282+12 plates. (London: Chapman and Hall, Ltd., 1936.) 10s. 6d. net.

THE fact that this work has necessitated four editions in fourteen years shows that it is fulfilling a definite need. Designed to illustrate methods commonly used in the best London practice, and clearly illustrated and set out, it can be recommended with confidence not only to students of quantity surveying, but also to the practitioner.

The Synthesis of Large Molecules*

By Prof. H. Mark, University of Vienna

NORMAL molecules with which the organic chemist has been concerned for many years, and which have led to an enormous number of interesting and important chemical combinations with valuable properties, have molecular weights between 50 and 2,000. Only a very few of them are smaller and few are larger, but even then they do not exceed these limits by a considerable amount.

For some time, it has been known that certain types of chemical reactions lead to products which do not crystallize and to which therefore was attributed the name of 'resins' or 'resin-like' substances. To identify and reproduce them was very difficult; hence for a long time it was considered that they could not be taken as objects for scientific investigation. But these substances offered mechanical, thermal and electrical qualities which made them very important from the technical point of view, and interest in their structure and synthesis began to develop.

On the other hand, the study of such natural products as cellulose, proteins, rubber, starch, silk, chitin, etc., led to the conclusion that their structural principles were the same as those of the synthetic resins; and the interest in this group of bodies was intense in view of their biochemical and technical qualities. Therefore a number of scientific workers began to investigate large molecules with enthusiasm; and our knowledge of them has rapidly increased.

It was found that two types of large molecules exist, one with chain-like molecules, another with large molecules which have the structure of a two- or three-dimensional network. In both cases, the number of atoms which are held together by normal chemical main valencies is very large—between 10^3 and 10^4 —and hence their molecular weight lies between 10^4 and 10^6 ($O = 16$). Several other qualities of these large molecules have been studied and cleared up; for example, their shape, reactivity, mechanical and optical behaviour, etc.

After our knowledge on the outstanding qualities of these bodies had reached a certain point, interest was aroused in that type of chemical reaction by which such macro-molecules are built up, and it is proposed to give a very short survey of the present state of evidence of this kind of chemical reactions, the so-called *polymerization* and *polycondensation* reactions.

* Friday evening discourse delivered at the Royal Institution on April 22.

THE POLYMERIZATION REACTION

Small organic molecules with one or more double bonds have the peculiarity of polymerizing under certain conditions of temperature, pressure, etc. This polymerization leads mostly to macro-molecular substances, which are therefore also often called *high polymers* or *high polymeric substances*. Let us consider the most simple chemical molecule with a double bond, namely, ethylene and its derivatives.

In this case the total polymerization reaction (of an ethylene derivative) is given by the relation

In this equation, X signifies the substituent ($\text{H}, \text{CH}_3, \text{Cl}, \text{C}_2\text{H}_5, \text{OH}$, etc.), n is a number of the order of magnitude between 10^3 and 10^4 . The left side of the equation (1) represents a great number of *independent small* molecules, each of which is completely known regarding its structure and contains a double C-C linkage. The right side gives a large molecule, the structure of which is not quite clear in all its details, which contains all the atoms contributed by the n molecules linked together by main valence bonds.

Frequently the macro-molecules built up from ethylene monomers are *chains*, and in such cases one may write equation (1) in more detail thus:

In this case, a certain assumption is made as to the internal structure of the chain-like macro-molecule, an assumption which is justified in some cases by considerable experimental evidence. Many chain polymerization processes were carried out with substances of this kind and formulated by relations of type (2), and it may be pointed out that Staudinger in Germany and Carothers in the United States especially have worked systematically in preparing macro-molecules by the aid of such processes.

Besides the material which is built up hereby, and which at first absorbed the whole attention of investigators, the *mechanism of the process* by which such long chains are formed is also of great interest and hence should be studied systematically. We have therefore in Vienna in the last five years carried out some series of experiments to elucidate

the different steps of typical polymerization reactions.

From the beginning, it is clear that the numerous independent particles on the left side of equation (1) cannot be linked together in *one single* collision process, which would have a vanishing probability, but that there must be a kind of growth, which builds up the long chain. This *growth process* is the aim of our studies; it seems to be not only of scientific interest in connexion with the physical-chemical problem of reactivity, but also of technical and biochemical importance. The technical significance may be confirmed by the fact that a great number of synthetic high polymers are of considerable interest, such as artificial rubber, insulators, varnishes, etc., while the biochemical importance is indicated by the observation that our own bodies and the skeletal substances of all plants and animals are built up of high polymeric substances and that therefore the growth processes of organized Nature may be connected with the reactions studied. In any event, a profound knowledge of the simplest polymerization reactions will be indispensable for the understanding of natural growth. We thought, therefore, that it might be worth while to devote some work to a thorough investigation of the kinetics of polymerization.

The general situation was not unfavourable: the kinetics of normal chemical reactions even of a rather complicated type was cleared up recently to a considerable extent by such scientific workers as Abel, Bodenstein, Bonhoeffer, Hinshelwood, Polanyi, Rideal, Semenoff, H. S. Taylor and others. The experimental procedure is not too complicated and the methods of following gradually the rate of the process are more or less worked out. Besides our own studies (carried out in the Chemical Institute of the University in Vienna by Breitenbach, Dostal, Jorde, Marecek, Pilch, Raff, Rudorfer and Sues) in the last four or five years, authors such as Bawn, Chalmers, Flory, Melville, Norrish, Rideal, Schulz, Taylor, Vernon and others have contributed valuable results, and one can summarize the present state of our knowledge in the following way.

(1) The whole polymerization process is very *complicated*, even when only chains are built up, and depends to a high degree on such experimental conditions as temperature, pressure, solvent, presence of catalytically active bodies, etc. But in the simpler cases—and only these have been studied carefully up to date—one can always distinguish three typical steps in a reaction of this kind.

(a) *The building of germs or nuclei.* No polymerization can take place if there is not an *initiation process*, by which unsaturated and highly

reactive 'germs' are formed. This process can be monomolecular, bimolecular or of another order, and furnishes the *centres* of growth. It consists in the fact that in a certain molecule a very high amount of activation energy or unsaturation is concentrated either by impact with another particle of high energy, or by absorption of a photon or by the formation of an intermediate combination. In any event, this *germ-building reaction* is rather slow and very dependent on the temperature or on the presence of a catalyst (including light).

This first step has been called the 'starting' process, and we can formulate a thermal bimolecular starting reaction, for example,

where the nucleus on the right side has two free chemical main valencies and therefore represents a very high free energy. Consistent observations by different workers led to the conclusion that the *activation energy* of the starting reaction in the case of polymerization of ethylene derivatives lies between 20,000 and 30,000 cal. per mol. The reaction is therefore slow and the germs are produced with a limited velocity.

(b) *The reaction of growth.* If an unsaturated germ is formed in the solution, there are two possibilities for its further fate. It may collide with another molecule (monomeric substance or solvent) and be *deactivated* by the impact. In this case, the nucleus just produced is annihilated again and no polymerization is started. But the germ may also *react* with the colliding particle and, if it is a monomeric molecule, may add it according to the relation:

This is a '*growth step*' and processes of this type lead to the result required, namely, to long chains, supposing that they follow one another very quickly. Really high polymeric bodies can only be formed when a slow germ production is followed by a quick growth reaction.

In fact the rate of reaction (b) is very much higher than that of (a). Measurement shows that (b) goes at least 10^4 -fold quicker than (a); every nucleus is built, begins at once to grow, and rapidly gives a chain of considerable length. This high velocity is easily understood: the free valencies at the end of the germ and of all intermediate members of the growing chain represent a high energy, and therefore the activation energy of the addition reaction (b) is rather low, lying between 4,000 and 8,000 cal. per mol., and explains the rapid growth, which is nearly independent of

temperature. Very interesting results concerned with the steric factor of growth would lead us much too far and cannot be considered here.

If the growing chains meet no obstacle during their period of adding monomolecular material, they will grow so long as molecules of the polymerizing substance are available, and the result of the whole process will depend only on the velocity of *germ formation*, k_1 , and of *growth rate*, k_2 . The competition of these two influences was discussed quantitatively by Dostal and Mark, and formulae have been derived and compared with the experimental results. It seems that only in very special cases one can reduce the whole complicated polymerization process to these two steps alone; mostly it is necessary to take into account a third elementary effect, which interferes with these two steps, namely, the *breaking-off* of the growth.

(c) *Breaking-off processes and sudden finishing of growth.* Our general knowledge of addition reactions between molecules shows that with increasing size of the reacting particles the probability for a successful collision, that is, the addition of a new member in the chain, decreases very rapidly with increased size of the molecules, even if the activation energy remains quite constant. Investigations of Evans, Eyring, Hellmann, Polanyi, Syrkin and Wassermann show that the reactivity falls off very quickly even with medium molecular weight (200-400). It is therefore to be expected that the rate of growth would be very much dependent on the actual chain length, an influence which was introduced into the formulae by Dostal and Mark, with the consequence that the growth-rate of an individual chain falls off slowly. Comparison with experiment showed that under certain conditions the polymerization of styrene seems to be remarkably influenced by this peculiar effect.

On the other hand, one must be aware of the fact that a *third type of reaction* finishes the growth of the chains by annihilating the active groups at their ends. Thus we have to introduce a third reaction constant, k_3 , which summarizes all possibilities for the saturation of the reactive spots. They are rather numerous, and it is therefore difficult to get a clear idea of the chain-breaking process.

(1) When the chains are flexible, it may happen that the two free valencies on their ends react with one another producing a ring molecule of many members. Such molecules are known from the work of Müller, Ruzicka and others, and even the kinetics of their formation was cleared up to a certain degree by Freundlich and Salomon. We do not yet know exactly how much this factor influences a given polymerization reaction, because we have no effective means of finding out how

many ring molecules are present in the product of a particular polymerization reaction. In this connexion, new experimental evidence is wanted; such a breaking-off reaction would be monomolecular.

(2) A growing system can lose its active ends, if a hydrogen atom wanders along the chain and if a double bond is formed at one end:

The probability of such *isomerization* will be inversely proportional to the actual length of the chain, and a breaking-off reaction of this type will be of the first order, short chains being in greater danger of undergoing this isomerization than longer ones. Actually, in the case of short chains ($n=2$ or 3), the final products of this reaction could be isolated in one or two cases, but it is not yet clear what role this type of chain-cutting plays in the whole process.

(3) The annihilation of a single active group at one end of the growing thread-like molecule can also be accomplished during a collision according to the equation

Here the hydrogen atom H^* jumps under the influence of the collision with M from the penultimate carbon atom to the colliding particle M , and a double bond is formed. Several types of this reaction have been discussed by Dostal, Flory, Mark and Schulz. The probability of such a process is proportional to the concentration of the unsaturated ends and to the concentration of M . The latter partner may be any molecule able to take up a hydrogen atom present in the reacting system, for example, a normal monomeric particle, another growing chain, a solvent molecule or any impurity of the solution. Even the wall of the vessel could produce the change expressed by the relation (d). Therefore it is not easy in a given case to say precisely what will happen.

An important and interesting question is: What happens to the energy which is set free by the process (d)? As a new C-H bond is formed, we may estimate the energy excess of (d) to be about 70,000 cal. per mol. It may remain in the chain and increase its internal vibrations and rotations; perhaps with the effect that after a certain average life-time the second end of the chain is also stabilized by a similar action. But the energy may also be transferred to M and create a highly active particle. If M is a monomeric molecule, it can be transmuted into a new germ, so that one chain is ended by (d) but another is started. There are signs that something like that happens under

certain experimental conditions. If M is a solvent molecule, the energy may be dissipated by consecutive collisions, but it may also be attached to one monomeric particle in the course of reproduction of a germ with the aid of the solvent. In recent papers of Dostal, Flory, Mark, Schulz and others, these various possibilities are discussed and brought into relation with the experimental facts.

The result is that at present no polymerization process can yet be resolved quite clearly into all its elementary steps, but there is no doubt that the three above-mentioned processes, namely, chain start, chain growth, and chain ending always take the outstanding role during a polymerization reaction. Increasing experimental material will enable us to separate more and more neatly the different possible steps and to work out something like a fine structure of polymerization reactions.

POLYCONDENSATION REACTIONS

This is the second type of reaction by which high polymers can be produced. Here also we will confine ourselves to reactions which lead to pure chain polymers. In a condensation reaction a new molecule is built by removal of a part of the reactant particles; this part is usually water. If a dibasic acid, for example, succinic acid, reacts with glycol one gets:

This esterification leads to a molecule which can again react with an alcohol or with an acid, producing further reactive molecules and growing thus *slowly* to a long chain with alternate alcohol and acid members.

Reactions like this have been investigated recently by Dostal, Flory, Marecek, Raff and others. They are much easier to deal with because the intermediate products are not unsaturated but of the same type as the monomeric substance. It is therefore not a chain reaction, which we have before us, but a *stepwise esterification* for which kinetic formulæ can be derived without serious difficulties. The problem of the mutual interaction of three different elementary processes as it has to be solved in the case of polymerization is here reduced to the mathematical study of a step reaction with many steps. The production of 'germs' is here of the same order of magnitude as the velocity of growth, and therefore the chains which are formed are much shorter than in the case of polymerization. Therefore a fairly good agreement was obtained by comparing the results of experiments with the above-mentioned formulæ, and the problem of polycondensation reactions does not offer serious difficulties to a quantitative understanding.

This is a reason why the efforts of workers are being more and more concentrated on the study of polymerization processes, which still offer a great number of unsolved and interesting problems.

The Solar Eclipse of June 19, 1936

AN old practice was revived on May 27, when a joint meeting of the Royal Society and the Royal Astronomical Society was held to receive reports on the expeditions organized by the Joint Permanent Eclipse Committee of the two societies for the total solar eclipse of June 19, 1936. It was sad to observe that on this occasion the tradition by which the president of the Royal Astronomical Society sat facing the audience alongside the president of the Royal Society was allowed to lapse.

Prof. F. J. M. Stratton opened the discussion with an account of the expedition to Kamishari in Hokkaido, staffed from the Solar Physics Observatory, Cambridge, with the addition of Dr. T. Royds, of the Kodaikanal Observatory, sent by the Government of India. He mentioned that the site was chosen after consultation with the Meteorological Office and consideration of the data supplied by the National Research Council of

Japan. Unfortunately, the prevailing wind which should have given the desired weather for the eclipse chose the wrong week to prevail, and the day of the eclipse was cloudy. The second half of the partial phase was happily clear, and Dr. Royds was enabled to carry through most of his programme successfully; second contact was observed through gathering clouds which spoilt by scattering light the programme of observing intensities of chromospheric spectral lines at different heights above the sun's limb, though flash spectra were obtained; within five seconds of the commencement of totality the sun was completely covered by cloud too thick even for the infra-red cameras to penetrate; the sun did not emerge into a clear sky until 10 minutes after the end of totality.

It was unfortunate that the half of the eclipsed sun which was in clear sky for second contact and for the first few seconds of totality was on the

opposite limb to that of second contact, and valuable observations were lost by a margin of seconds only in the race of moon and clouds to cover the sun. Prof. Stratton devoted his remarks to the part of the programme which was lost due to the clouds—the polarization of the coronal light to be observed by Dr. C. W. Allen with a double camera and a Nicol prism in front of one lens, and the direction of polarization of skylight in the neighbourhood of the eclipsed sun, to be observed photographically by himself and visually by Dr. F. W. Aston with a set of Nicol prisms and Savart plates. Prof. Stratton paid a tribute to the generous help and assistance received from the Japanese authorities and scientific colleagues, and mentioned that, of the three neighbouring Japanese expeditions, all of whom had a clear sky for the eclipse, one was led by Prof. Matsukuma, of Sendai University, who had stood down from his original plan to go to Kamishari to make room for the English party.

Dr. Royds next gave an account of his measures of the displacement of the Fraunhofer lines at the centre and limb of the sun's disk with and without an eclipse. His values were as follows:

Intensity of lines	Mean displacement to red			
	Without eclipse		During eclipse	
	Centre A.	Limb A.	Centre A.	Limb A.
11.0	0.0100	0.0122	0.0078	0.0125
5.2	0.0084	0.0148	0.0068	0.0151
3.0	0.0050	0.0123	0.0068	0.0116

It was clear from Dr. Royds' eclipse observations that the values obtained from the limb without eclipse had not been seriously affected by light scattered from the bright centre of the disk, which would especially affect the weak lines. Observations had been made at distances from the centre of the sun's disk of 0, 0.28, 0.57, 0.76, 0.90, 0.95, 0.97 times the sun's radius: the observation at 0.992 and the hoped-for observation of chromospheric lines were lost owing to clouds. The explanation in terms of convection currents for lines of different intensities originating at different levels in the sun, which had been offered for the discrepancies at the centre of the sun, could not hold for the limb, and the divergencies from the predicted Einstein displacements had yet to be explained.

Dr. R. O. Redman discussed the advantages from spectrophotometry of the chromosphere of a jumping slit spectrograph (taking a series of exposures with a fixed plate) over a continuously moving slitless spectrograph: there was less trouble from scattered light, higher resolution, greater purity of spectrum, and no trouble such as arises from the varying width of the steadily narrowing crescent photographed with the slitless

instrument. He described the moving back camera specially designed by Mr. C. R. Davidson and himself for the eclipse, the instrumental set-up, and the programme of exposures at intervals of one second carried out at the eclipse through second contact. As defined by the final disappearance of the Fraunhofer spectrum, totality commenced 1 second late on the computed time.

Dr. A. D. Thackeray gave an account of the flash spectra secured by Dr. Redman with the moving plate camera and by himself with the Hills quartz spectrograph fed by light from an aluminized mirror. While in both cases the original plan of observing the changes of intensity of spectral lines with solar heights had to be abandoned because of light scattering by the clouds, yet much of value could be learned from the plates. In particular, Dr. Redman's spectra included one of the finest for the study of the transition from absorption to emission spectra that had ever been secured. He directed attention to the following points of special interest: (a) the presence of a bright line at 3969.40 Å. between $H\epsilon$ and $[H]$ never previously recorded in flash spectra and evidence of the excellent definition secured by Dr. Redman; (b) the presence in absorption of the subordinate series $3^1P^o - \pi^1S$ of Na at a stage where the D lines had practically vanished in transition from absorption to emission; (c) the displacement towards the violet of emission lines compared with the absorption lines in a spectrum taken at a distance 0.9994 r from the centre of the sun's disk; (d) the gradient of the Balmer series in emission from $H\beta$ to $H26$, with a value of lower weight for the total emission of $H\alpha$: the gradient showed manifest departure from the values given by the Schrödinger-Pauli formula, as had been found by Davidson and Stratton in the 1926 eclipse.

Prof. J. A. Carroll described the equipment of the expedition from Aberdeen to Omak: the objective interferometer prepared for a monochromatic image of the whole corona crossed by interference rings which should show by their displacements internal movements in the corona; a high-dispersion echelon spectroscope with 35 plates immersed in fluid and giving an effective thickness to each plate of 1 mm. in air; and a spectrograph for the extreme infra-red spectra of the corona and chromosphere. He then dealt in detail with the method of reducing the daily range of temperature of 12°C. to the range that could be allowed without loss of definition for the instruments, 0.1° for lenses and prisms, 0.01° for the interferometer and 0.001° for the echelon. Large thermal inertia in the optical parts and small and slow changes in the surround of each instrument were required. The hut was doubled-walled and

lagged inside; it was also equipped with heating and refrigerating plant controlled by thermostats and by fans for stirring the atmosphere. The instruments in their turn were surrounded by a further lagged cover with again a thermostatically controlled heating circuit inside. This first serious attempt at delicate temperature control under eclipse camp conditions had worked very successfully.

Mr. E. G. Williams spoke of the results obtained with the infra-red spectrograph. A composite plate had been used of special rapid panchromatic for 5800-6700 Å., Agfa 800 for the 8000 region and Agfa 950 for the region beyond 9000 Å. It had been intended to use Agfa 1050 for the region beyond 10,000 Å., but though the plates were specially flown over from Berlin to Moscow they were no longer sensitive when the day of eclipse arrived and could not be used. They were, therefore, unable to secure the lines at 10,748.80 Å., 10,797.95 Å. recently reported by Iyot. They did get a line at 7591.3 Å. in the coronal spectrum for which Curtis and Babcock in 1928 gave the

wave-length 7896 Å. and Iyot more recently from the Pic du Midi gave 7891.9 Å. No trace was found of the line about 9609 Å. to be expected if the coronal spectrum came from a doubly excited helium atom. In the chromospheric spectrum lines of the Paschen series were obtained, for the first time at an eclipse, from P4 to P17, and other lines were identified as due to He, O, Mg and Ca⁺.

In the subsequent discussion Mr. J. Evershed, referring to Dr. Royds' excellent spectra, pointed out that to reduce his shifts from an arc in air to an arc *in vacuo* meant an increase of 0.003 Å. and meant that the displacement at the limb was twice the predicted Einstein value. Prof. A. Fowler, in sympathizing with the Cambridge party on their failure, said that it was a magnificent failure. He was very much impressed by the mechanism of Dr. Redman's camera and with the very interesting and beautiful results he had obtained. He would also like to congratulate Mr. Williams on his infra-red spectra.

Obituary Notices

Prof. A. G. Perkin, F.R.S.

PROF. A. G. PERKIN died at his Leeds residence on May 30. Born at Sudbury, Middlesex, in December 1861, he was the second son of the late Sir William Perkin, brother of the late W. H. Perkin, jun., Waynflete professor of chemistry in the University of Oxford, and half-brother of the late Dr. F. M. Perkin, who was well known as a consulting chemist.

A. G. Perkin grew up in an atmosphere of chemistry and zeal for scientific investigation. His education was varied: he followed in his father's footsteps by attending the City of London School, and from 1877 until 1879 studied under Frankland and Guthrie at the Royal College of Chemistry, South Kensington, where he carried out the investigation leading to his first paper, "The Action of Nitric Acid on Di-p-tolylguanidine", communicated to the Chemical Society in 1880. He next spent a year at Anderson's College, Glasgow, under E. J. Mills, and finally a year in the Dyeing Department, Yorkshire College, Leeds, where he worked with J. J. Hummel on new compounds derived from the colouring matters of brasilwood and logwood. Perkin always paid generous tribute to the abilities and personality of Prof. Hummel, to whom he owed his first, and lasting, enthusiasm for the study of the natural colouring matters.

In 1882 Perkin left the Yorkshire College to take up an appointment as chemist at the alizarin factory of Hardman and Holden, Ltd., Manchester, and was

promoted to the position of manager in 1888. During this commercial period he continued scientific investigations and published papers on the action of nitric acid on anthracene, and in collaboration with W. H. Perkin, jun., on derivatives of anthraquinone, and on the colouring matter of the Indian dyestuff, kamala.

Perkin resigned his position with Hardman and Holden, Ltd., in 1892 to join the staff of the Dyeing Department, Yorkshire College, as lecturer and research chemist. Then followed a period of more than twenty years of intensive research, mainly concerned with the isolation of the colouring principles of natural products and the investigation of their constitutions. The profound knowledge of natural colouring matters that he gained by his brilliant researches established his international reputation in this field. He examined numerous natural colouring matters by degradative methods, and in certain instances deduced their constitutions, many of which, for example, those of catechin, luteolin, gossypetin, quercetagetin, etc., have since been confirmed synthetically by other workers.

In later years, Perkin devoted more of his time to the chemistry of anthraquinone derivatives. A study of the migration of the acyl group in partially acylated phenolic compounds led to the synthesis of, *inter alia*, some hydroxyanthraquinone methyl ethers, originally isolated from the Indian natural dyestuff, chay root, but not hitherto obtained synthetically. The constitutions of numerous hydroxyanthranols were

established by conversion into corresponding benz-anthrone and examination of the methylation products of the latter. The formation of hydroxy-anthracenes, -dianthrone, -dianthraquinone, -dianthraquinonyls and -helianthrone also was investigated and the constitutions of these compounds established.

Perkin's original papers, including those published in the *Proceedings of the Chemical Society*, all of which did not appear afterwards more comprehensively in the *Transactions*, exceeded 270. He was also author of numerous articles on natural colouring matters in "Thorpe's Dictionary of Applied Chemistry", and, in collaboration with Dr. A. E. Everest, he published the classical monograph "The Natural Organic Colouring Matters" in 1918.

Perkin was elected a fellow of the Institute of Chemistry in 1887, a fellow of the Royal Society of Edinburgh in 1893, a fellow of the Royal Society in 1903, and was awarded the Davy Medal of the Royal Society in 1924. He was also a vice-president of the Society of Dyers and Colourists, and a member of the Biochemical Society, the Chemical Society, the Pharmaceutical Society, Society of Chemical Industry, the Textile Institute, and the Livery of the Worshipful Company of Leathersellers.

In 1916, Perkin succeeded A. G. Green as professor of colour chemistry and dyeing in the University of Leeds. During the Great War he carried out investigations for the Ministry of Munitions, and also directed the work on intermediates and synthetic dyes carried out by the colony of research chemists of British Dyes Ltd. in his Department.

During his professorship, Perkin did much to widen the fundamental education of his undergraduates and to enhance the reputation of his Department as a scientific training ground for recruits for the dyestuffs, dyeing and allied industries. The very large number of students who entered for courses in colour chemistry and dyeing in the immediate post-War years were attracted at least as much by the opportunity of working under him as by the popular appeal of these subjects at that time. His students were very successful in securing appointments on completion of their courses and most of them now occupy important positions in industry.

Perkin exerted a profound, but unobtrusive, influence on his colleagues and students. He was a very gentle man with a most charming and lovable personality. He did most of his work with his own hands, and it was a privilege to observe him at work in his laboratory. He was not only a great chemist in his generation, but also he was so imbued with a passionate zeal for unravelling the secrets of Nature that all who came in contact with him were inspired by his pioneering spirit.

On his retirement in 1926, Perkin was accorded the title of emeritus professor, and in 1927 the University of Leeds conferred upon him the degree of D.Sc., *honoris causa*. In fact, he never retired, for he continued to prosecute his researches without any interruption in the professor's laboratory in the Colour Chemistry and Dyeing Department of the University of Leeds until his health began to

fail in February this year. At that time he was endeavouring to determine the constitution of a green vat dye which he had obtained some years previously by heating the hydroxylated anthranol, derived from alizarin, with tetrachlorothiophen and an alkylating agent.

Perkin was well known in the Isle of Man, for many years spending all vacations at his house at Port Erin, and he was a governor of King William's College. He was very fond of animals and took the greatest interest in his dogs, his pony and his tortoise. He also inherited a great love of music, and was an accomplished performer on the flute and bassoon; he was a leading member of amateur orchestras in Yorkshire. He married Annie, daughter of the late J. E. Bedford, of Leeds, who survives him. There were no children.

E. J. CROSS
F. M. ROWE.

Prof. S. H. Langdon, F.B.A.

THE study of Assyriology must nowadays be held to embrace, in principle, the whole of the archaeology, history, culture and languages of ancient western Asia. In this immense field the labourers are still few, and no country can at present boast more than a handful of them. The loss of any one is therefore serious, since replacement, much less reinforcement, is problematical. That loss is the more sensible when so active a worker as Prof. S. H. Langdon, professor of Assyriology in the University of Oxford, is withdrawn by death, on May 19, at the early age of sixty-one years.

Since the boundaries of the study have been so vastly extended by recent discovery, it has become inevitable in Assyriology, as in other sciences, that a man should specialize. Langdon's chosen branch was Sumerian, the primitive language of Babylonia, virtually extinct by the end of the third millennium B.C., but of paramount importance as belonging to a people who have been revealed, time and again, as the originators of most of the vital elements in the whole pre-Hellenic culture of western Asia. At the time when Langdon was beginning his career, knowledge of this language had scarcely passed the stage of entire dependence upon the translations furnished in bilingual texts by late Assyrian scribes, while the scepticism of Halévy still preoccupied the minds of many. Some of Langdon's early work, however, was devoted to the Sumerian religious texts without Semitic translation which have survived in large numbers, and because of their great difficulty of interpretation still remain to-day among the obscurest parts of the literature written in cuneiform.

This observation is, of course, in itself a criticism of Langdon's achievement, for throughout his working life it was upon these texts that his abundant energy was mainly concentrated; editions of the originals and translations make up a large part of his bibliography, whereas few of his contemporaries cared to venture upon so hazardous a ground. But it must be owned that, in the editions, his copies were not always of the most reliable, and that he failed to detect this

and other faults in his translations (though never unready to admit mistakes) chiefly because of a certain lack in comprehension of the practical sense of a phrase or of a text, and this allowed him too often to put forward merely verbal translations. It must be remembered, however, that some of the literature to which he devoted himself is jejune in content, and must necessarily look rather absurd in the baldness of translation. How carefully he had prepared himself for this work is shown by his "Sumerian Grammar" (1911), which, if it cannot be said to have marked a decisive advance, has the credit of being the first full-length treatment of the subject.

To the study of the Akkadian (Semitic) language, which is better known, Langdon's contributions were less copious. But he has to his credit at least one book which is still a standard work of reference, "Die neubabylonischen Königsinschriften" (1912) and, despite certain oddities, his "Babylonian Epic of Creation" (1923) contains much which subsequent translators have been glad to use. Besides one or two philological books of less importance he wrote in 1931 a general work on "Semitic Mythology" which, somewhat belying its name, drew very largely upon the Sumerian religious literature which he knew so well. But many will think that one of Langdon's

most remarkable achievements was that he, essentially a man of the study who had hitherto shown little interest in archaeology, seized the opportunity after the Great War to excavate in Iraq, and with great enthusiasm proposed, organized, and even raised part of the money for, an expedition which made important discoveries at Kish. He himself spent two seasons on the site, much to the detriment of his health, and afterwards began two series of volumes devoted to the archaeological and epigraphical results of the work. In his latest years he often spoke of a Sumerian dictionary which he had long been preparing, and he had announced a future edition of the Assyrian texts upon which his recent Schweich lectures were based.

We regret to announce the following deaths:

Prof. A. Erman, formerly director of the Egyptian Section of the Berlin Museum, and professor of Egyptology in the University, on June 26, aged eighty-three years.

Dr. H. H. Jeffcott, secretary of the Institution of Civil Engineers, on June 29.

Prof. T. Mather, F.R.S., emeritus professor of electrical engineering in the City and Guilds (Engineering) College, Imperial College of Science and Technology, on June 23, aged eighty-one years.

News and Views

Queen Mary and the Bodleian Extension

QUEEN MARY was given a warm and affectionate welcome when, on June 25, in royal weather, she visited Oxford to lay the foundation-stone of the great Bodleian extension to be erected in Broad Street opposite the Clarendon Building. A special Convocation of members of the University was held in the Sheldonian Theatre to which the public were admitted without ticket, and which was so filled in every part that although no one was turned away, twenty more could not have been accommodated in comfort. There an address of thanks was presented to Queen Mary by the Chancellor, Lord Halifax, and the Vice-Chancellor, the Master of Balliol. They spoke of how proud Oxford is of its ancient, Bodleian library, and how urgent it is for the work now being done in all branches of teaching and research that it should be properly maintained and extended. The Queen then crossed Broad Street to a stand raised above the enormous hole in the ground which is at present the site. There was assembled another large party representative of Oxford life, academic and civic, and of those entrusted with the erection of the building, Sir Giles Gilbert Scott, the architect, was present. The Queen then laid the foundation-stone on which the following words have been inscribed:

ÆDIFICII NOVI BODLIANI
HVNC PRIMVM LAPIDEM
POSUIT MARIA REGINA
REGIS GEORGII VI MATER
DIE XXV MENS. IVN. A.D. MCMXXXVII

Prof. F. Wood Jones, F.R.S.

PROF. FREDERIC WOOD JONES, at present professor of anatomy in the University of Melbourne, has accepted an invitation to fill the chair of anatomy in the University of Manchester, in succession to Prof. J. S. B. Stopford, who has asked to be relieved of the duties of the chair, in view of the increasing responsibilities of his administrative work as vice-chancellor of the University. Prof. Wood Jones graduated in science in the University of London in 1903, and in medicine and surgery in 1904. In 1910 he was awarded the degree of D.Sc. in zoology of the University of London. He was elected to the Royal Society in 1925 and to the fellowship of the Royal College of Surgeons in 1930. Prof. Wood Jones has held professorial chairs in the London School of Medicine for Women (anatomy) and in the Universities of Adelaide (anatomy), and Hawaii (physical anthropology) in addition to the chair of anatomy at Melbourne, to which he was appointed in 1930. In 1932-33 he acted as temporary director of the Peiping Union Medical College. His experience in other fields includes the duties of a medical officer in the Far East, anthropologist to the Egyptian Government, and membership of the Archaeological Survey of Nubia. On four occasions he has delivered the Arris and Gale Lectures of the Royal College of Surgeons. Among his numerous published works are "Coral and Atolls", "Arboreal Man", "The Mammals of South Australia" and "Man's Place among the Mammals".

Sir Morell Mackenzie (1837-1892)

SIR MORELL MACKENZIE, the eminent throat specialist of the Victorian era, was born at Leytonstone, Essex, on July 7, 1837. He came of a medical family, his father being a distinguished general practitioner, and his younger brother Stephen a prominent physician on the staff of the London Hospital. After qualifying in 1858, he went to Paris, where he attended the clinics of Trousson, Nelaton, Ricord and others, and then to Vienna, where he studied under Oppolzer, Skoda, Rokitsansky and Hebra, and finally to Budapest, where he made the acquaintance of Czermak, who was experimenting with the laryngoscope invented by Manuel Garcia. On his return to London, after holding the posts of resident medical officer and registrar at the London Hospital, he set up in practice in George Street, Hanover Square. In 1863 he gained the Jackson prize of the Royal College of Surgeons by an essay on the pathology and treatment of diseases of the larynx and in 1866 was appointed assistant physician to the London Hospital, becoming full physician in 1873. His chief publication was his work on "Diseases of the Throat and Nose", of which the first volume appeared in 1880 and the second in 1884, and at once became the standard book on the subject. He was also the author of "The Use of the Laryngoscope in Diseases of the Throat" (1865), "Diphtheria: Its Nature and Treatment" (1879) and "Hay Fever and Paroxysmal Sneezing", of which the fourth edition was published in 1887.

MACKENZIE'S eminence as a specialist won him many distinctions. He was elected an honorary member of the medical societies of Vienna, Budapest and Prague and one of the two foreign honorary fellows of the American Laryngological Association. In 1887 he was knighted, and in 1888 he received the Grand Cross and Star of the Royal Order of Hohenzollern for his attendance on the Emperor Frederick, the story of whose illness he relates in the book entitled "The Last Illness of Frederick the Noble", for which he incurred the censure of the Royal Colleges. Though a strong advocate for specialism in medicine, as he showed by two articles published in the *Fortnightly Review* in 1885, Mackenzie always maintained that a very complete medical training should be the basis of education for the specialist. Apart from his literary work, Mackenzie deserves to be remembered for his addition of a large number of instruments to the armamentarium of throat surgery and his skill as an operator in the removal of laryngeal growths. Like many other celebrated men, Mackenzie was the subject of asthma, from which he suffered for thirty years, and his death at the comparatively early age of fifty-five years took place on February 3, 1892.

Acculturation and Native Policy

In commenting on the recent debate in the House of Lords on policy in native administration in the Empire (see *NATURE*, June 26, p. 1083) it was urged that the contribution of anthropological science

should not be overlooked when the possible effect of administrative action, and its bearing on future policy were under consideration. A concrete example of the results which may be expected to emerge from such scientific investigation of the effects of cultural impact on a relatively simple people is afforded in a study by Prof. I. Schapera of the BaKxatla, a Bantu-speaking people, who migrated from the western Transvaal to evade the Boers about 1840 and settled in what afterwards became the Bechuanaland Protectorate. Here their earlier contact with Western civilization was continued, at first through missionaries, and afterwards through traders and administrative officials. Prof. Schapera in this study ("Contributions of Western Civilization to Modern Kxatla Culture", *Trans. Roy. Soc. S. Africa*, 24, 3) analyses both the acceptances and the rejections by the BaKxatla of elements of Western culture and their consequences, with the somewhat remarkable result that he finds that, while some traditional elements of their own culture are retained and new elements from Western culture are incorporated with little change, an entirely novel cultural pattern is also growing up out of the contact. His paper must be consulted for details, but one instance may be mentioned. As a result of the introduction of Christianity, ancestor worship has virtually died out, but magic is retained. At the same time, the Christianity which is their official religion has come to be something very different from the doctrine as it was first introduced among them. Although it is not possible to generalize from one African tribe to another without testing the premises of the argument, it is clear that investigation on these lines has been shown to be essential before the risk is run of making any fundamental changes of principle or detail in policy.

School of Colonial Administration at Oxford

ANTHROPOLOGISTS will be afforded an opportunity of bringing these and kindred matters to the notice of administrative officers of the Colonial Services at the Oxford University Summer School of Colonial Administration, which will meet at St. Hugh's College, Oxford on July 3-17. The arrangements have been made in connexion with the Social Studies Research Committee of the University. The School is intended primarily for the benefit of members of the Colonial Administrative Services, more especially, though not exclusively, those serving in Africa. The problems of native administration in tropical Africa will be discussed in a series of lectures, in which they will be brought into relation on broad lines with world problems of economics and politics; while the experience of other countries in tropical administration in relation to such matters as local government, education, elementary and adult, the co-operative movement and the like will be demonstrated. Leading foreign experts will lecture on a number of other topics, and more especially on methods of native administration in territories under other than British rule. The School will be opened by the Right Hon. W. G. A. Ormsby-Gore on July 4, and on the same day an inaugural address will be delivered by Lord Lugard. Among those who have promised to take

part in the proceedings and discussions are Sir Alfred Zimmern, Sir Arthur Salter, Lord Lothian, the Warden of All Souls, and Sir Donald Cameron. A number of anthropologists have been invited to join in the discussions and talks, dealing with problems affecting administration in different regions and from different aspects. About one hundred and seventy officers on leave have intimated their intention of attending the School. Although not 'official', the School has had the cordial support and assistance of the Colonial Office.

An Astronomical Jubilee

LA SOCIÉTÉ ASTRONOMIQUE DE FRANCE, the creation of Camille Flammarion, who did so much to popularize astronomy in France, has recently celebrated its jubilee. The chief event in the festivities which were held to commemorate the occasion was a great reception on June 16 in the Great Theatre of the Sorbonne, at which nearly three thousand people were present; the President of the French Republic attended and the Minister of Education, M. Jean Zay, presided. M. Jules Baillaud, the present president of the Society, gave an account of the history of the Society and of the work done for it successively by Camille Flammarion and his widow. After a short address by the Minister of Education, Prof. C. Fabry gave a charming account of the progress or revolution in the astronomical outlook in the past fifty years, and some beautiful slides which had been taken by Mr. Ritchey and by M. de Kerolx at Fourcalquier were shown by M. Baldet. A film was shown of Camille Flammarion's activities in connexion with the Society, and a recorded speech of his was repeated to the audience. A concert followed in which artists from the Opera assisted, while at an earlier stage artists from the Comédie-Française and elsewhere recited poems and read extracts from Camille Flammarion's works. A memorable evening, such as could scarcely have been held anywhere outside Paris, concluded with some ballets danced by pupils of the late Lote Fuller.

THE celebrations were attended by astronomers from Belgium, Czechoslovakia, Denmark, Great Britain, Italy and the United States to add their greetings and congratulations to the Society, its president and its secretary, Madame Camille Flammarion. Opportunity was taken of the presence of many astronomers in Paris for a discussion on various aspects of the problem of interstellar matter in space, which is to be the subject of a conference in Paris on July 11-17 at the Institut Henri Poincaré. Messrs. M. G. Darmois, J. Baillaud, Lacroute, F. Perrin, Chalonge, Barbier and Mineur gave an account of the present state of our knowledge on interstellar calcium absorption in space, the structure of the galaxy, the nature and distribution of absorbing clouds and their effect on stellar spectra and colour indices.

Covent Garden Laboratory

For the last eleven years, contact has been maintained between the work of the Department of

Scientific and Industrial Research on the transport and storage of food and an important branch of industry through the Department's Covent Garden Laboratory in Endell Street, London. This Laboratory has provided an excellent place for keeping under survey the condition of produce passing through our markets generally and for diagnosing or tracing to their source the different types of wastage and deterioration in fruit and vegetables. Samples of fruits showing wastage or abnormal features are collected from the market or are brought to the Laboratory by salesmen. Often the trouble can be diagnosed at once, but sometimes it is desirable to get the diagnosis confirmed by the Low Temperature Research Station at Cambridge or the Ditton Laboratory. The Covent Garden Laboratory also receives for examination samples of consignments of fruits new or comparatively new to Great Britain, such as mangoes, mangosteens and papaws. The interest taken in this work has now made it necessary to leave Endell Street for larger premises, which were opened by Sir Frank Smith on June 28. These are situated on the top floor of Nos. 9-13 Kean Street.

THE new accommodation includes two chemical laboratories, a large 'ice box' for cooling fruit to -30° F. and three cold stores. One, maintained at 34° F., will be used for delaying ripening and for observations on apples; another at 45° F. for work on citrus fruits, and the third at 65° F. will be used as a conditioning room for initiating ripening. The two colder stores will also be used for studying the advantages of temporary cold storage for wholesalers or retailers, that is, storage of, say, mushrooms and melons for short periods. In the chemical laboratories estimations of the sugar and acid content of the fruit will be carried out. The sugar content of apples, of course, varies between individual specimens, and to get a representative sample the apples are frozen solid and then ground up into a fine powder. Another important measurement to be made is the rate of respiration of the fruit. This not only gives an indication of the age of the apple, but also is important in connexion with research which is being carried out on the mechanism by which sugar breaks down to carbon dioxide. The alcohol content of apples increases as they grow older, and this is also a subject of measurement, as it is hoped that this factor will prove an important diagnostic indication. Produce from the Empire overseas is inspected before being shipped in order that nothing may be exported which is not up to standard. Facilities will be available at the new Laboratory for officers of the Dominions and Colonies engaged in following up this work.

Medicine Stamp Duties

DUTIES in respect of medicines were first imposed so far back as 1783. The tax then was twofold, as it is to-day. It was imposed on all persons who sold medicines, not being doctors, apothecaries, etc., and secondly a duty was 'laid on the medicines' themselves when sold by such persons. A Select Committee

was appointed in November 1936 to consider the duties of excise chargeable under the Acts of 1802, 1804 and 1812, and any amendments thereto, and to report thereon and to make recommendations, and its report has now been issued (London: H.M. Stationery Office, 1937; price 3d. net). Complete abolition of these duties has been advocated, but the Committee recommends that the duties ought to continue and should apply to a wider field, and bring in a much larger revenue. At the same time, it recommends that the duty should be at the rate of twopence instead of threepence in the shilling, and should be graduated less steeply. The recommendations are of a far-reaching character, and bring in everything that looks like a drug or smells like one. As drafted, it would even seem that medicines prescribed or dispensed by medical practitioners are included, though it can scarcely be believed that this was intended. The Committee also sees no reason why the "modern chemist" should have "a very valuable preference" in the sale of preparations which claim the "known, admitted, and approved remedy" exemption which has hitherto enabled them to sell unstamped certain types of preparations liable to duty if sold by ordinary shopkeepers. Despite defects, the recommendations are on the whole in the interests of the public, and with certain amendments should prove acceptable.

Acquisitions at the British Museum (Natural History)

H.M. THE KING has presented to the Museum an exceptionally fine specimen of a black leopard from India. The skin is very dark and the spots are scarcely visible in certain lights. In March 1936, Mr. H. St. J. B. Philby set out on a journey through the districts of Asir and Najran in Arabia, returning to Jidda in the early part of this year. During this trip, Mr. Philby made large natural history collections which he has presented to the Museum. Apart from the birds which number 747 specimens belonging to some 100 species, the collections include mammals, reptiles, fishes, mollusca, a large number of insects, 250 botanical specimens, some minerals, and about 400 rocks. Among the birds, three are new to science, namely, a race of the common magpie, a small Scops owl, and an emerald cuckoo. His collection includes a number of eggs previously unknown. The Department of Entomology has received from Mrs. Tillyard a collection of 800 mayflies and 700 dragonflies which formed part of the late Dr. R. J. Tillyard's collection. Among the dragonflies are included the type specimens of 105 species, and among the mayflies of 8 species. This gift is perhaps the most valuable addition to the Museum collections in these groups that has been received for many years. Accessions to the Department of Geology include a collection of about 20,000 fossil invertebrates (including 60 type and figured specimens) from the Ordovician and Silurian strata of the Girvan district of Ayrshire. The collection was made by the late Mrs. Robert Gray of Edinburgh and her daughters. Mr. F. N. Ashcroft has presented a further series of 747 specimens from his collection of Swiss minerals.

Repton School Science Society

At the triennial conversations of the Repton School Science Society on June 25 and 26, some forty demonstrations were shown. In the biology section, a way of recording the heart beat of a frog and the effect of stimulation by nerves, by electricity and by drugs, was shown and also a collection of local zoological and botanical specimens. Recent developments in chemical industry were illustrated by the moulding of bakelite cups in a home-made electrically-heated press producing a pressure of $1\frac{1}{2}$ tons per sq. in., by the manufacture of rubber gloves from the latex by a simple dipping process using an experimental plant, and by electro-plating and bronzing on a semi-technical scale. A lecture was given in the physics section on electrical illumination, dealing with the development of lighting from the carbon filament lamp to the modern vapour discharge lamps. There were also demonstrations of a way of eliminating dazzle from motor-car headlights using the new polaroid screens and of a home-made model railway fitted with a system of automatic signalling and train control.

Scientific and Industrial Research in Australia

THE tenth annual report of the Council for Scientific and Industrial Research, Commonwealth of Australia, covers the year ended June 30, 1936, and in addition to reports on the five main divisions of the Council's work, refers to co-operation in research with New Zealand and to the meetings of the Standing Committee of Agriculture appointed as an advisory body to the Australian Council of Agriculture established in 1934 (Canberra: Government Printer, 1936. 4s.). Numerous reports to this Committee were furnished by the Council of Scientific and Industrial Research, dealing with such subjects as codling moth pest, survey of potato virus diseases, tobacco investigations, seed testing, weed pest investigations, soil drift, grasshopper investigations, etc. The Council also acts as a liaison with the Commonwealth Government on behalf of the Standards Association of Australia, and in this capacity provided reports on standardization of wearing parts of agricultural machinery, primary products, dusting sulphur, wire-netting and other galvanised products. During the year, the activities of the Council were extended to cover investigations into the problems of Australia's secondary industries, and a special committee has been set up to define the field and make recommendations regarding problems for investigation and the staff and organization required. A new Forest Products Laboratory approached completion during the year. This Division completed a full investigation of the veneer and plywood industry in Queensland with special reference to gluing practice, which has already led to a marked improvement in the quality of the products.

THE Division of Plant Industry has been responsible for work on the control of downy mildew of tobacco by benzene vapour in covered seed beds; this has made possible the prevention of a most destructive

disease which previously resisted all attempts at control. Considerable progress in the investigation on the control of the peach moth is reported by the Division of Economic Entomology and very favourable results have been obtained with nicotine-bentonite-sulphur sprays. The same Division has been responsible for work on termite control, while the work carried out on the control of weeds has been considerably extended by reorganizing the botanical and entomological phases in one section under joint control of the chiefs of the two Divisions. The Division of Animal Health Nutrition has been responsible for investigations on pleuro-pneumonia in cattle and on the treatment of internal parasites of sheep, while its fundamental investigations on the nutrition of sheep have already led to an increase of nearly 150 per cent in the yield of wool as well as to a remarkable variation in its character. Valuable contributions to viticulture and regarding the role of organic matter in plant nutrition have been made by the Soils Division, while the Food Preservation Section has obtained promising results in investigations on the storage of peaches and plums from the point of view of export to Great Britain which should decrease the wastage in export. The Radio Research Board has continued its investigations; appreciable advance in the control and eradication of prickly pear by biological methods is again reported, and a programme of fisheries research has also recently been initiated.

National and International Standardization

REALIZATION of the advantages of standardization of industrial materials and requirements has led in most of the industrially developed countries to the establishment of organizations to promote such standardization, and already a high degree of standardization has been reached in many countries. A most informative account of the work of the various national authoritative bodies engaged in this work is given in "A Survey of the Present Organization of Standardization—National and International", published by the World Power Conference. In Great Britain, the British Standards Institution is the national standardizing organization and is responsible for the determination of British standard specifications. Though the Institution has a strict rule that it does not initiate standardization but waits to be approached by a recognized outside authority such as a trade association, technical institution, or Government department, it has already issued more than 560 British Standard Specifications, exclusive of some 160 specifications for aircraft materials and components issued in co-operation with the Air Ministry.

INTERNATIONAL standardizing organizations, such as the International Federation of the National Standardizing Associations (ISA) or the International Electrotechnical Commission (IEC) have also been established. ISA, for example, federates the national standardizing organizations of nineteen countries and was founded in New York in 1926 with the object of

promoting co-operation, co-ordination and interchange of information. But international co-operation, in contrast to the development of standardization along national lines, has made slow progress. It was indeed the need for further development in this direction that led the International Executive Council of the World Power Conference to initiate this inquiry, and the report has been published with the hope that it may serve as a stimulus to a greater degree of co-operation in national standardization and to a closer co-ordination of the activities of international organizations engaged in standardization, to the end that duplication and overlapping may be avoided and international standardization may be more speedily effected.

Scientific Basis of Birth Control

In *Science and Society* of June–September 1937, there appears an article on "The Scientific Basis of Birth Control" by Dr. C. V. Drysdale, president of the Malthusian League. The author remarks that the true, present-day application of the Malthusian doctrine may best be understood by reference to the affairs of an ordinary married couple. "The average young man marries when his income is sufficient to support a wife and perhaps one child, and, if that income were fixed, every additional child would mean a lowering of the family standard of existence." But, in many occupations, salaries rise with age and service, and if additional children come when there has been a sufficient rise in income, no lowering of the standard need take place. "This is the population problem as it confronts almost every middle-class couple." If children arrive at a greater rate than can be allowed for by increases of salary, then such a family is "over-populated". It amounts to this, that, in general, in civilized countries, birth-control has assisted in the preservation of the amenities and standards of living. Another aspect of birth-control is, of course, its application to what is called negative eugenics, that is, the avoidance of parenthood by persons afflicted with transmissible disease or defect. Dr. Drysdale looks forward to a future in which a planned social economy shall ensure general early marriage with reasonable family limitation. But it will be necessary to arrange that the limitation does not go too far, and the question is: How?

Fauna of the U.S.S.R.

SOME years before the Great War, the Russian Academy of Sciences launched an ambitious scheme of publishing detailed monographs on all groups of animals occurring within the Russian Empire and in neighbouring countries, under the title "Fauna de la Russie et de pays limitrophes". The programme of the publication was so extensive that the first few volumes which appeared were sufficient to show the virtual impossibility of continuing the work on the same scale. The idea, however, was not abandoned, and the Academy of Sciences of the U.S.S.R. has now commenced the publication of a new "Faune de l'URSS", which aims at giving a full, but concisely graphic treatment

of the systematics and distribution of all animals already found, or expected to occur, in the Soviet territories. Six volumes and two smaller parts, mostly dealing with insects, have already appeared, and they make a very good impression, particularly as regards the generally high scientific standard, although the paper, printing and illustrations might be improved. Unfortunately, not all the volumes are by outstanding experts in the systematics of the groups treated, and some have apparently been prepared by authors who may be excellent specialists, but not in the groups they had to monograph. All foreign zoologists will be pleased to see that each volume has a very full summary in a Western language, in which all determination keys, new descriptions and more important notes are given. Since the "Fauna" covers the whole of extra-tropical Asia and eastern Europe, its value for systematists working on the palaearctic region will be inestimable, and volumes on their respective groups will be eagerly awaited by all zoologists.

The Botanical Society of Edinburgh

THE *Transactions and Proceedings of the Botanical Society of Edinburgh*, 82, Part 1, 1936, is a particularly interesting number, including as it does the record of the centenary meeting of this Society. The main contribution is in effect a local flora—a list of the flowering plants and ferns from Fife and Kinross by William Young. The address delivered by Prof. F. O. Bower at the centenary meeting is included. No more appropriate speaker could have been found for that interesting occasion, and his appreciation of botanical progress during the period of activity of the Society could only have been delivered by a veteran whose reminiscences still feed his botanical enthusiasm. Prof. Bower points out how plant physiology has gained since 1836 by the precision that can now be assigned to the medium in which vital functions are proceeding, through the advances in cytology and anatomy. With arresting phrase and breadth of vision, in a few pages the main movements of botanical thought during the century are brought before the reader. The last half century, it is pointed out, because it is an age of specialization, has increased the need for the services of such general societies as the Botanical Society of Edinburgh. Prof. Bower indicates how the 'herd sense' among his fellow botanists is probably responsible for the temporary ascendancy of one field of investigation, thus leading to "multiplying instances of what has been already demonstrated". He then shows himself fully aware where the 'herd' is gathering now when he ends an eloquent plea for a modern morphology, based upon developmental studies of the meristem, with the speculation that hormones may then prove the key to unlock those phenomena of symmetry that are expressed in appendages. The Botanical Society of Edinburgh began principally as a means to the formation of a herbarium for its members, and has taken a prominent part in the creation of the magnificent herbarium that is now housed at the Botanic Gardens.

Giorgi's System of Units

DR. A. E. KENNELLY recently presented a report, from the historical point of view, to the Society for the Promotion of Engineering Education, in regard to the adoption of the M.K.S. (metre-kilogram-second) system of units ("The M.K.S. System of Giorgi as adopted by the International Electrotechnical Commission (I.E.C.) in June 1935"). Dr. Kennelly has done his work well, giving a fair statement of the present position. Unfortunately, physicists and engineers are not yet agreed as to the best system of units to adopt. Many of them are in favour of following Heaviside and completely rationalizing the system of units. Others are more conservative, and think that the change, although saving much arithmetic, would scarcely be worth the labour involved in learning all the relations connecting the new and the old units. The two leading organizations are in agreement that a fourth unit is theoretically necessary to link internationally adopted electrical units with the dynamical units of the M.K.S. system. They agree that this fourth unit may preferably be 'space permeability' taken at the definite numerical value of 10^{-7} (unrationalized). This report of Dr. Kennelly's can do nothing but good.

Prohibition and Cirrhosis of the Liver

At an address given at the recent annual meeting of the Royal Institute of Public Health at Margate, Dr. C. C. Weeks stated that, in the United States, when prohibition really was prohibiting, there was a marked decrease in the death-rate from cirrhosis of the liver and a rise as 'boot-legging' became more extensive. The liquor sold under 'boot-legging' conditions was much more alcoholic than usual, ethyl alcohol being so high as 70 per cent in much of the whisky sold. There was consequently a good deal of acute alcoholism attributed to all sorts of causes, whereas the one effective cause was that the whisky was 50 per cent stronger than usual. Since the repeal of prohibition, there has been a slight but steady increase in deaths due to alcoholism. Official figures for 1935 showed that, out of 24 States, 20 had an increase in the death-rate from cirrhosis, while only 11 showed an increase in the death-rate for alcoholism as compared with 1932. The steady drinking of a more normal alcoholic beverage was leading inevitably to more cirrhosis of the liver but to less acute alcoholism.

Society of Chemical Industry: Food Group

At a recent meeting of the Food Group of the Society of Chemical Industry, it was decided, in view of the growing interest in food science and the diversity of the subject, to form panels within the Group. These panels will be responsible for directing the activities of the Group in connexion with their respective divisions of the science. The first two panels, of which there will be several, are now in process of formation, namely, a nutritional panel and a microbiological panel.

Studentships and Fellowships for Medical Research

THE Medical Research Council invites applications for a second series of studentships and fellowships for research into disease together with experimental work of an immediately relevant kind. Six post-graduate studentships are offered for medical graduates who have already held house appointments and are strongly inclined to a career in clinical science or experimental pathology. Each selected student will receive an inclusive grant at the rate of £200 per annum, during a period not exceeding twelve months, for personal maintenance while undertaking approved courses of study in Great Britain such as may be regarded as best calculated to advance the student's training in methods of research. Four research fellowships are also offered for candidates of similar qualifications who have already had some experience in the use of research methods. Each fellowship will be tenable for one year at the ordinary value of £250 per annum, and will be renewable in approved instances at the rate of £300 per annum for a second year. These fellowships are intended as probationary appointments for research in clinical science or experimental pathology. Further information can be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, London, S.W.1.

Announcements

SIR WILLIAM BRAGG, president of the Royal Society and director of the Royal Institution, has been elected an honorary associate of the Royal Institute of British Architects.

By an order of the Committee of Privy Council, Mr. W. M. Goodenough has been appointed a member of the Medical Research Council on the retirement of the Right Hon. Lord Mildmay of Flete. Mr. Goodenough also succeeds Lord Mildmay as treasurer of the Council.

THE Howard Prize for 1937 of the Royal Meteorological Society has been awarded to Cadet Ralph Wills of H.M.S. *Comboy* School Ship. Cadet Julius Cornel Donner and Cadet John Easton Neils Carter of H.M.S. *Worcester*, were placed second and third respectively. The subject of the essays was "The Meteorology of the Voyages of Discovery to America and to South Africa".

ON the occasion of the seventy-fifth birthday of Prof. E. Leclainche and of his election to the presidency of the Paris Academy of Sciences, the National French Syndicate of Veterinarians recently organized a ceremony in his honour. Prof. Leclainche is honorary director of the French Veterinarian Services and president of the International Office of Epizootics.

PROF. KARL NEUBERG, founder and editor of the *Biochemische Zeitschrift* and formerly director of the Biochemical Institute of the Kaiser-Wilhelm Gesellschaft, celebrates his sixtieth birthday on July 29. An issue of the periodical *Enzymologia*, with which he is associated, is to be published in honour of this anniversary; more than seventy authors, chiefly his pupils, have contributed to the number.

It is announced by the New York correspondent of *The Times* that a fund of about £2,000,000 for cancer research has been given to Yale University by Mr. Starling W. Childs. It is to be called the Jane Coffin Childs Memorial Fund for Scientific Research, and the deed of gift provides that, if the problem of cancer should be solved, the Foundation is to devote itself to other unsolved medical problems or to problems in other fields of science.

A GENERAL Discussion on reaction kinetics has been arranged by the Faraday Society, to be held in the Chemistry Theatre of the University of Manchester on September 13-15. As is usual at these discussions, a number of distinguished foreign investigators have agreed to take part. Further particulars can be obtained from the Secretary, Faraday Society, 13 South Square, Gray's Inn, London, W.C.1.

READERS interested in psychology may like to know that a Graphological Society has been formed, and the first public meeting will take place in October. The honorary secretary is Mrs. Paula Friedenham, 50 Heathway Court, West Heath Road, London, N.W.3.

THE second Congress of the Austrian Society of Röntgenology will be held in the Central Röntgen Institute of the General Hospital at Vienna on July 10-11. Further information can be obtained from the Secretariat, Zentral Röntgen Institut, Allgemeines Krankenhaus, Alserstrasse 4, Wien IX.

AN institute for anatomy, physiology and hygiene is shortly to be opened at Riga.

DR. THEODOR VAHLEN, professor of applied mathematics at Berlin, has been made an honorary professor in the University of Greifswald.

THE fourth International Leprosy Congress will be held at Cairo on March 21, 1938. Further information can be obtained from the Secretary, 131 Baker Street, W.1.

R270

THE Congress of the International Union of Towns will be held in Paris on July 5-10, when a discussion will be held on the campaign against smoke in various countries, and other subjects. Further information can be obtained from M. R. Hummery, 28 rue de Liège, Paris.

WE have received List No. 25, a catalogue of old medical books, issued by Messrs. E. P. Goldschmidt and Co., Ltd., 45 Old Bond Street, London, W.1. Among 214 items, are several early works on bacteriology and parasitology of Behring, Ehrlich, Köch and Laveran, and a collection of French X-ray photographic prints, made about 1890. It also includes a copy of the rare third edition of Harvey's "De Motu Cordis", a first edition of Laennec's "De l'Auscultation mediate", and early works on anaesthesia, ophthalmology, pharmacology and physiology.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 31.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Use of the Name 'Racemic Acid'

THE discovery of racemic acid by Karl Kestner or Koestner, a chemical manufacturer at Thann, in the Vosges, and the elucidation of its relationship to ordinary tartaric acid, more especially by Gay-Lussac, Berzelius and Pasteur, constitute one of the most important episodes in the history of organic chemistry. Upon an account of the nature of racemic acid there is no need, and we do not intend, to enter here; but, owing to the confusion which exists in chemical literature regarding the authorship of the name *racemic acid* (variously attributed to Gay-Lussac, Gmelin and Berzelius), a note on this subject may be of interest to students of the history of chemistry.

The author of the term *racemic acid* is Gay-Lussac. The first occurrence of the term in print is found in a publication, "Cours de Chimie par M. Gay-Lussac, comprenant l'histoire des sels, la chimie végétale et animale", published in Paris by Pichon et Didier, in 1828. In the "Summary" at the beginning of the 24th Lecture, one finds the term, "Acide racémique", and on p. 23 one reads: "Ce serait ici le lieu de parler de l'acide racémique". The mis-spelling which is found here, *racémique* (with or without the accent) in place of *racémique*, finds its explanation in the fact that the "Cours de Chimie" was reproduced from shorthand notes of the course of lectures "professés à la Faculté des Sciences" by Gay-Lussac, and published without the co-operation or sanction of the lecturer. Gay-Lussac, in fact, protested vigorously against this *nouveau genre d'industrie*, which had arisen in Paris, of publishing the lectures of certain professors without their permission or supervision. "Je ne sais", wrote Gay-Lussac¹, "jusqu'à quel point il est juste de s'approprier ainsi des leçons publiques, contre la volonté même des professeurs; . . . Mais il n'est pas indifférent que l'on sache que je n'ai pris aucune part à cette nouvelle spéculation de librairie . . . Je déclare donc que mes leçons de chimie sont imprimées contre mon gré; que j'ai refusé les épreuves qu'on m'a offertes pour me faire coopérer à leur publication, et que je n'y prends absolument aucune part."

Meanwhile, the publishers had issued a note that "le désir que nous avions de terminer la publication de cet ouvrage presque aussitôt que le Cours du Professeur; la promptitude avec laquelle il a fallu par conséquent corriger les épreuves; et d'ailleurs la nécessité où nous fûmes de recourir à une autre personne que le Professeur, pour faire cette correction à laquelle il ne voulait pas se livrer lui-même, ont été cause que plusieurs fautes d'impression se sont glissées dans quelques-unes des Livraisons que nous avons envoyées à nos Souscripteurs." The text was

read by M. Gaultier de Claubry and a list of errata was drawn up. In this list, *racémique* is corrected to *racémique* (without an accent on the e). The unaltered text, however, was republished, with its errors, in 1833 by the firm of de Just Rouvier et E. Le Bouvier, Paris.

The authorship of the term, *acide racémique*, is established also by a footnote which appears in the French translation² of Berzelius's original Swedish paper. The French translation is entitled: "Composition de l'acide tartarique et de l'acide racémique (traubensäure), etc", and the footnote to this reads: "M. Gay-Lussac a donné, en 1828, le nom d'*acide racémique* à l'acide dont il est ici question." Thomas Thomson, who made an examination of racemic acid³, also states in his "Chemistry of Organic Bodies. Vegetables" (1838), p. 66: "This acid has been described in the Chemistry of Inorganic Bodies (Vol. ii, p. 69) under the name of *vinic acid*. But the term *racemic acid*, given it by M. Gay-Lussac in 1828, is better."

While the authorship of the specific term *acide racémique*, applied to the isomer of tartaric acid which Berzelius, in 1830, proposed to call *paratartronic acid*⁴, must undoubtedly be attributed to Gay-Lussac, the general application of the term racemic to the optically inactive, resolvable isomer of a substance, must be credited to Pasteur⁵.

With regard to the position of Gmelin and Berzelius in the naming of the acid called racemic by Gay-Lussac, the facts are as follows. Walchner, in 1827, had carried out an investigation of racemic acid and its salts⁶, and his results were communicated in Gmelin's "Handbuch der theoretischen Chemie", 3rd Edit., vol. 2, p. 53 (published in 1829). Here the acid is called, for the first time, *Traubensäure*; and in his paper communicated to the Swedish Academy of Sciences, Berzelius (p. 64) states: "Gmelin har gifvit den namnet drufsyra, Traubensäure". In this same paper, Berzelius suggested the name paratartronic acid, and this name was widely used. To sum up. To the acid discovered by Kestner and first called by John, "Säure aus den Voghesen", Gay-Lussac, in 1828, gave the name, *acide racémique*. In 1829, Gmelin called it *Traubensäure* (rendered by Berzelius in Swedish as *drufsyra*), and, in 1830, Berzelius called the acid, *acidum paratartronicum*.

Measurement of the Nuclear Absorption of Electrons by the Atmosphere up to about 10^{10} Electron-Volts

ACCURATE observations on cosmic ray intensities as measured by Neher electroscopes have been made in the equatorial belt (Madras, India, mag. lat. 3° N.) and in San Antonio, Texas (mag. lat. 38.5° N.) up to between 98 and 99 per cent of the way to the top of the atmosphere. The most significant results of these measurements may be summarized as follows:

(1) Cosmic rays, whatever their nature, are so rapidly absorbed as a whole in the outer layers of the atmosphere that even in the equatorial belt, where the effect of the earth's magnetic field upon them is a maximum, they get into equilibrium with their secondaries and produce their maximum ionization before they have penetrated through the first tenth of the atmosphere. (This effect was suggested as a possibility by Millikan and Cameron in 1927¹ in their report made at the Leeds meeting of the British Association on their first voyage (1926) made from Los Angeles to Peru to look for the effect of the earth's magnetic field on incoming electrons. The words then used were: "If the northern hemisphere and the southern hemisphere curves [of ionization with altitude] coincided, it would go a long way toward eliminating the possibility that the rays are generated by the incidence of high-speed beta rays on the very outer layers of the atmosphere. . . . For such beta rays would be expected to be influenced by the earth's magnetic field so as to generate stronger radiation over the poles than over the equator". This is precisely what the present experiments show to be the case for the whole field-sensitive portion of the cosmic rays.)

(2) From that point on, they fall off exceedingly rapidly in intensity, following an exponential equation, their law of absorption being like that of X-rays and not like that of particles that exhibit range phenomena such as low-energy beta rays, proton rays or alpha rays.

(3) The depth beneath the top of the atmosphere at which the maximum ionization is attained, always less than a tenth of an atmosphere, changes but slightly in going from San Antonio, where no electrons of energy less than 6×10^6 electron volts can get vertically through the blocking effect of the earth's magnetic field, to Madras where no electron-rays of energy less than 17×10^6 electron-volts can similarly get through.

(4) The difference between the San Antonio and the Madras curves makes possible for the first time the determination of the complete curve of ionization produced in the atmosphere by incoming charged particles contained within a sharply limited band of energies having a weighted mean value of 10×10^6 electron-volts.

(5) Down to a depth of a third of an atmosphere from the top (3 metres of water) this curve is in good agreement with the Bethe-Heitler theory of nuclear electron absorption as recently extended by Carlson and Oppenheimer as well as by Bhabha and Heitler.

(6) The exceedingly rapid absorption of this latitude-sensitive radiation, with an absorption coefficient which is nearly constant and independent of incident energy, qualitatively justifies the 'shower theory' of Millikan and Cameron as the main cause of the ionization of the atmosphere produced by incoming electrons even of this huge energy.

(7) The latitude-sensitive part of the cosmic ray ionization found in the lower part of the atmosphere

is considerably more penetrating than is predicted by the foregoing extended Bethe-Heitler theory of electron absorption; nevertheless, while at a distance of one twentieth of an atmosphere from the top, these 10×10^6 electron volt field-sensitive rays are producing 160 ions per c.c. per sec., at sea-level their total ionizing influence has fallen to but 0.3 ion per c.c. per sec., that is to less than 1/500 of its value near the top of the atmosphere.

(8) The two foregoing results in (7) show that the process of nuclear absorption of electrons is more complicated and involves the production of more penetrating secondaries than is pictured in the simple physical assumptions underlying the Bethe-Heitler theory, but, at the same time, that the whole progeny of secondaries, whatever their nature, has been reduced almost to zero by the time sea-level has been reached, not more than about one tenth of the sea-level ionization being accounted for by field-sensitive rays at all.

(9) The latitude-sensitive part of the cosmic ray ionization found in the lower atmosphere is practically all due to the secondary effects of varied nature resulting from the absorption of the incoming electrons in the upper tenth of the atmosphere.

(10) The apparent absorption coefficient, namely, 0.54 per metre of water, of the actual curve representing the whole progeny of secondary influences resulting down to sea-level from the absorption of incoming electrons in the very top layers of the atmosphere is approximately the same as that found by Johnson and by Neher for the east-west effect, thus proving that the particles causing the latitude and the east-west effect are of the same type. Both absorption coefficients are such as to suggest that these particles are electrons (predominantly positive), not protons.

Longitude Effect and the Asymmetry of Cosmic Radiation.

IN a recent letter, Dr. M. S. Vallarta¹ has emphasized the discrepancy which arises from the comparison of the variation of intensity of the cosmic rays along the magnetic equator (longitude effect) and the position of the magnetic centre of the earth as determined from magnetic observations. According to Hoerlin, the longitude of the magnetic centre as determined by cosmic rays should be 100° E. instead of 160° E. as found directly.

The theory according to which the cosmic ray observations are interpreted is that the angle of opening of the cone $\pi/2 + \theta$ must be computed by Störmer's formula

$$\sin \theta = \frac{2}{r} - \frac{1}{r^2},$$

with a value of $r = r_0(1 - \rho \cos L + \dots)$ proportional to the distance to the magnetic centre and therefore dependent on the eccentricity ρ of the dipole and on the difference of longitude L reckoned from the dipole (positive towards the east).

It should be noted that the angle θ in Störmer's formula is reckoned, not from the vertical of the place

but from the line joining the dipole to the point of observation. If we take account of this circumstance, we find that the change of the angle of opening becomes

$$\Delta\theta = -\alpha\rho \cos L + \rho \sin L;$$

where the first term is the effect due to the change of distance from the dipole and the last term is the new parallactic effect. The coefficient

$$\alpha = \frac{2}{r_0} \left(\frac{1}{r_0} - 1 \right) / \cos \theta$$

varies with the energy of the rays. For the rays just able to come from the zenith ($\theta = 0$), it is equal to 4 and its minimum value is $\sqrt{2}$.

For negative particles, the angle of opening of the cone must be taken not from the west but from the east, and therefore the sign of the new term must be inverted. The usual theory is therefore correct only if the rays are a mixture of positive and negative rays in equal amount. This is not the case, as the asymmetry measurements have shown that the positive rays are more important.

If we write $\tan \beta = 1/\alpha$ we get

$$\Delta\theta = \frac{-\rho}{\sin \beta} \cos(L + \beta),$$

showing that the improvement of the theory essentially amounts to reckoning the longitudes from an origin at an angle β west of the position of the dipole. This angle β , which is 0 for rays just able to reach the equator, is 14° for rays of 0.5 Störmer, that is, 15×10^6 eV. (for protons) and goes up to 36° for the limiting case of 60×10^6 eV. Although this correction is far from the 60° asked for by Hoerlin, it is in the right direction and will substantially reduce the discrepancy between theory and observation.

The fact that the longitude effect is different according to the effective value of the intensity of the rays and therefore according to the screens used, and also depends on the sign of the charge, will make the analysis more difficult; but when it is achieved, due to improvement in observations and also to progress in the working out of the details of the theory, it will probably afford information on the sign of the charge and the distribution of the intensity of the rays.

Crystallization of Lysozyme

THE occurrence in nasal mucosa of a substance capable of lysing certain bacteria was noted by Fleming¹, and this or a similar compound was later obtained from egg-white by Wolff² who, however, did not recognize the true chemical nature of the substance. Meyer, Thompson, Palmer and Khoraso³, adopting an entirely different procedure, showed that lysozyme is a protein giving some of the typical reactions; they also quoted analytical data.

Dr. E. A. H. Roberts, of the Department of Pathology, has further improved the technique of the preparation and his results will shortly be published in another place. In the meantime we have undertaken the purely chemical side of the investigation of this interesting protein, and we wish to express our gratitude to Dr. Roberts and Prof. Florey for the facilities provided.

The material made according to the method of Roberts seems to possess a high degree of homogeneity and it may be crystallized by one operation from solution in $N/20$ acetic acid and concentration over aqueous potassium hydroxide in a vacuum desiccator. The crystals (Fig. 1, photomicrograph by Mr. H. M. Powell) appear to be dodecahedra, and Miss D. Crowfoot has kindly undertaken their crystallographic examination.

Crystalline lysozyme is about as active as the Roberts specimen in bringing about lysis of *Micrococcus lysodeikticus*, but comparisons by the method used are not capable of great accuracy.

Fig. 1.

Mr. H. S. Philpot has kindly studied the behaviour of lysozyme in the ultracentrifuge, and the molecular weight appears to be of the order of 18,000, a quite provisional estimate.

The ultra-violet absorption shows the usual tyrosine-tryptophan band at about 2770 Å. in acid solution; this is shifted to about 2870 Å. in $N/10$ sodium hydroxide solution. Using the method of Holiday⁴, analysis of the curves indicates the presence of 4.4 per cent of tyrosine residues and of 2.2 per cent of tryptophan residues in the molecule.

Thermal Decomposition of Ethylene Bromide

WHILE we were investigating the behaviour of certain gaseous alkyl and alkylene bromides at high temperatures, with the view of finding out how the energy of activation was related to the zero point energies (or vibration frequencies) of adjacent bonds (for example, tert.-butyl bromide with three C-C bonds might be expected to require a less activation energy than normal butyl bromide with two C-H and one C-C bonds) we found that the homogeneous nature of the decomposition could not always be predicted, and that the calculations made for ethylene bromide ($C_2H_4Br_2$) by Sherman and Sum¹ based on the Eyring method were somewhat misleading.

We used an all-glass pyrex apparatus, with a diaphragm gauge (electrical contact) balanced against a mercury manometer. The decomposition of ethylene

bromide took place in a pyrex vessel immersed in a molten metal bath. The temperatures ranged from 340° to 400° C. and were controlled by a chromel-alumel thermocouple and potentiometer system. At 340°-370° the decomposition is heterogeneous; the introduction of pyrex glass tubing leads to considerable increases in the reaction velocity. The final pressure is double the initial pressure, the products of decomposition are vinyl bromide (C_2H_3Br) and hydrogen bromide, and the reverse reaction is not appreciable at these temperatures. The reaction follows the first order equation very well.

There is no decomposition into ethylene and bromine. The calculations of Sherman and Sun lead us to believe that the decomposition into ethylene and bromine would take place at an appreciable rate at 350° with an activation energy of 50,000 calories. We have calculated an approximate activation energy for the heterogeneous reaction of about 30,000 calories.

Since the ethylene bromide molecule prefers to dissociate into vinyl bromide and hydrogen bromide, we would be inclined to look for some structural explanation of this phenomenon. The *trans* form of ethylene bromide is considered to be the more 'stable' (preferred) form, even at high temperatures¹. This interesting theory may explain how it is that ethylene bromide can become attached to the surface in such a way as to give rise to these decomposition products. It is very different from the behaviour of ethylene iodide ($C_2H_4I_2$), where an iodine atom (or an adsorbed iodine atom) acts as a catalyst for the decomposition into ethylene and iodine². Also, the molecule decomposes homogeneously into the same products. Here one of the iodine atoms in the molecule acts as a sort of 'intramolecular catalyst'. One would expect the *cis* form of ethylene iodide to be its normal condition, but there do not appear to be any definite data on this point. Recently, however, the idea that ethylene iodide dissociates directly into ethylene and iodine has been disputed³.

Further data and experimental details will be published shortly.

Pyruvic Acid Dehydrogenation, Vitamin B₁ and Cocarboxylase

It had been found by Davis¹ that pyruvic acid is oxidized by the acetone preparation of *Bacterium Debrückeri*. This preparation has proved to be very useful for a closer study of pyruvic acid dehydrogenation².

A coenzyme could be removed from the acetone-treated lactic acid bacteria by washing with phosphate of pH 8. The washed preparation was activated by the addition of decoctions of animal tissues (kidney, brain, liver). The addition of vitamin B₁ was without effect. Therefore cocarboxylase was tried, which had been found by Lohmann to be a vitamin B₁ pyrophosphate³. A pure preparation of cocarboxylase was

most kindly supplied to me by Dr. K. Lohmann, with which the following experiment was carried out.

Activator	None	Kidney decoction	30% cocarboxylase
Oxygen consumed in 30 minutes (c.m.m.)	8	137	175

The effect of cocarboxylase is surprising, because no decarboxylation to aldehyde and carbon dioxide was found with the bacteria. Pyruvic acid was broken down only by dehydrogenation to acetic acid and carbon dioxide.

With highly concentrated organ extracts, the activation found was notably higher than with cocarboxylase at saturation. Probably the additional activation is due to the presence of flavin phosphate in the concentrates. A highly purified, but not pure, preparation of flavin phosphate from heart together with cocarboxylase gave the same additional activation.

Furthermore, it was found that no dehydration takes place with the complete system in the absence of free phosphate. Phosphate is easily removed from the acetone preparation by washing with an acetate mixture of pH 4-7. The effect of phosphate is shown by the following experiment.

Phosphate (10 ⁻⁴ M. per lit.)	0	1.4	2.8	5.5
Oxygen consumed in 60 minutes (c.m.m.)	9	45	79	132

Phosphopyruvic acid was found to be inactive as hydrogen donor.

In the ocatatorulin test of Peters⁴, free vitamin B₁ activates pyruvic acid oxidation with brain tissue. But from certain experiments, Peters *et al.* concluded that after the addition of vitamin, a substance α is converted into γ , γ being the activator of pyruvic acid oxidation. The experiments reported here suggest that the α of Peters is vitamin itself and the γ vitamin pyrophosphate, into which it is converted by the tissue.

Crystals with Vitamin K Potency

THE evidence for the existence of anti-haemorrhagic vitamin (K) required by the chick for preservation of normal blood clotting time has been reviewed in a former paper¹.

This vitamin has been obtained in a crystalline fraction isolated from concentrates obtained in molecular distillation by cooling such concentrates in absolute methanol with solid carbon dioxide. The colourless crystal fraction obtained by this method was recrystallized from methanol three times by the same cooling procedure. Two such lots of crystals have been obtained.

The first lot was found capable of restoring normal blood clotting time within four days when added to the basal deficient diet given to five chicks with clotting time greater than 30 minutes. The second lot, tested by preventive assay, maintained normal

blood clotting time in chicks when added to the basal diet, while the clotting time of chicks receiving no vitamin K supplement was in every case greater than 30 minutes.

Some vitamin still remained in solution. On the basis of comparative clotting times, the crystal fraction was approximately eight times as potent as the fraction not crystallized out by cooling with solid carbon dioxide.

Effect of Hetero-auxin on the Growth of Broad Bean Plants in Water Culture.

HITCHCOCK and Zimmerman¹ induced responses in the shoots of tomato and tobacco plants by applying a solution of hetero-auxin to the soil. These responses included bending, swelling, the production of adventitious roots on the stems, and epinasty of the leaves. This letter describes the relative effect of adding small amounts of hetero-auxin to the culture solution bathing the roots, and spraying approximately the same quantity on the shoots by the method described by Pearse². *Vicia Faba* (Dobbie's Champion Long Pod) was used as the test plant, and

Fig. 1.

THE SHOOTS OF THE PLANTS ON THE LEFT HAVE BEEN SPRAYED WITH HETERO-AUXIN, THOSE IN THE CENTRE ARE THE CONTROLS, WHILE THOSE ON THE RIGHT HAVE BEEN SUPPLIED WITH HETERO-AUXIN IN THE CULTURE SOLUTION TO THE ROOTS.

the seedlings were three weeks old at the time of the first applications of hetero-auxin; the shoots were then about 10 cm. high. Fig. 1 shows the result of one week's treatment; the plants on the left were sprayed daily with 1 c.c. of a 0.01 per cent solution of hetero-auxin, those in the centre are the controls, while those on the right were supplied daily with 1 c.c. of a 0.01 per cent solution in 500 c.c. of culture solution.

In Table 1 the average total length of lateral root for three plants, and the average dry weights of root and shoot are given.

Fig. 1 and Table 1 show that supplying hetero-auxin to the solution has retarded the growth in length of the roots, although the total root weight is practically unaltered, while spraying the shoots with hetero-auxin has slightly decreased the weight of root growth without altering its form. The shoot growth was retarded by both treatments, but whereas spraying induced swelling of the stem and epinasty of the leaves, the plants receiving hetero-auxin in the culture solution did not exhibit any such symptoms. The immediate effects of the treatments therefore appeared to be strictly local in each case, and the subsequent retardation of the growth of the parts of the plants other than those receiving the hetero-auxin would seem to be due to an alteration in the dynamic equilibrium of the plant, rather than to its movement within the plant body. The movement of hetero-auxin from the soil into the shoots of tomato plants noted by Hitchcock and Zimmerman¹ may have been due to the much greater amount of hetero-auxin applied.

TABLE 1.

Series	Total length of lateral root (cm.)	Root dry weight (mgm.)	Shoot dry weight (mgm.)
Control	335.4	356	917
Shoots sprayed daily with 1 c.c. of a 0.1 per cent solution of hetero-auxin	356.3	335	680
1 c.c. of a 0.1 per cent solution of hetero-auxin added daily to culture solution	180.6	352	642

The terminal bud was inhibited by spraying, an effect previously noted by Pearse³ when spraying tomato plants with phenylacetic acid, and with indolebutyric acid. Thimann and Skoog⁴ caused inhibition of the lateral buds of plants of *Vicia Faba* by applying hetero-auxin to the cut-off stump of the terminal bud; but here it has inhibited the growth of the terminal bud itself.

A full account of this work is being prepared for publication.

Skatole as a Root Forming Substance

The activity of skatole as a growth-promoting substance has been noted by Glover¹. We have carried out experiments which show that skatole accelerates root formation in cuttings. Cuttings of *Leptospermum scoparium* and of *Ficus repens* were treated with an aqueous solution of skatole in the manner described by Hitchcock and Zimmerman², and the cuttings planted in a mixture of coco-nut fibre and sand in a propagator. The treatment accelerated root production. With *Leptospermum scoparium* cuttings, treatment for six hours with skatole solution of a concentration of 20 mgm. per 100 c.c. on March 19 gave 60 per cent of the cuttings well rooted in 20 days. A control set showed 30 per cent only of the cuttings to be slightly rooted. With

Ficus repens, a more marked response was obtained. Cuttings planted on April 22 and examined after 19 days showed in the control set 10 per cent rooted with an average of 0.3 roots per cutting and an average length of root per cutting of 1.6 mm. Of cuttings treated for 3 hours with a skatole solution of a concentration of 20 mgm. per 100 c.c., 90 per cent were rooted with an average of 4.2 roots per cutting and an average length of root per cutting of 38.4 mm.

Parallel experiments showed L-tryptophane to be inactive.

Function of the Gills of the Mayfly Nymph, *Closon dipterum*

It is generally supposed that the plate-like abdominal gills occurring in some ephemeropterid nymphs are respiratory organs, although little experimental evidence is available to support this view. Moreover, both Dewitt¹ and Cuenot² have shown that these gills are not essential to life. Recently, another function has been ascribed to these structures by Eastham³, who shows that in the nymph of the mayfly, *Ecdyonurus venosus*, they act as paddles which bathe with water the gill tufts attached to their bases.

In order to test whether or not these gill plates are truly respiratory in nature, the oxygen consumption of both the normal and gill-less nymphs of the mayfly, *Closon dipterum*, has been measured at 10° C. at various oxygen concentrations. The results are shown in Fig. 1, each point in which is the average of three to eight experiments. This figure may be compared with Fig. 1 of Fox, Wingfield and Simmonds⁴.

Fig. 1.

It will be seen that, as the oxygen content of the water is decreased, the oxygen consumption of both the normal and the gill-less nymphs remains nearly the same until a concentration of about 3 c.c./lit. is reached. Below this concentration the oxygen consumption of the gill-less nymphs falls off rapidly, but this marked decrease does not occur in the

normal animals until the oxygen content of the water is reduced to about 1.5 c.c./lit. It is clear that the gills in this species of mayfly nymph only aid the oxygen consumption in water of low oxygen concentration, that is, below 3 c.c./lit.

At high oxygen concentrations, the gills of *Closon dipterum* only beat intermittently, but as the oxygen content of the water falls the quiescent periods are much reduced, thus causing a greater volume of water to pass over the dorsal surface of the animal in a given time.

It is not yet clear whether at low oxygen concentrations the level of oxygen consumption in the normal animal is maintained by gaseous exchange taking place at the gill surface, or whether under these conditions the gills merely act as paddles which pass a greater volume of water over the respiratory surfaces of the animal. Either of these processes would enable the animal to maintain its normal level of oxygen consumption at low oxygen concentrations.

The results summarized above will be published in full elsewhere.

Zoological Nomenclature

IN spite of various criticisms, it must be admitted that the system of nomenclature used by zoologists and botanists is fundamentally sound and serviceable. Much depends, however, upon uniformity of practice, and certain irregularities which are becoming current are likely to cause serious confusion.

The International Code, Article 10, states: "When it is desired to cite the name of a subgenus, this name is to be placed in parenthesis between the generic and the specific names. Example: *Vanessa (Pyrameis) cardui*." The example is not well chosen, *Pyrameis* being a synonym of *Vanessa*; but the meaning is clear.

In the admirable *Review of Applied Entomology*, it has become the custom to cite an alternative generic name as if (according to the above rule) it were a subgenus. Thus, in the part for February 1937 we read "*Aonidiella (Oxytetranychus) aurantii*", for the red scale of the orange. *Oxytetranychus* is the older name, and opinions differ as to whether the red scale should be referred to that genus, with *Aonidiella* as a subgenus, or whether *Aonidiella* should be raised to full generic rank. The method of citation used by the Imperial Institute of Entomology, and indeed by others, would be intelligible were it not for the instructions given (following the usage of many decades) in article 10. If the method proposed in article 10 is abandoned, it is difficult to see how subgenera can be properly cited.

A quite different tendency, which seems to be on the increase, is to cite subgenera as if they were genera. An example (many more might be found) is furnished by C. Friek's "Horned Ruminants of North America", just published. A new subgenus *Stoeboceros* is proposed for *Tetrameryx conlingi* of Stock; but although

it is repeatedly stated to be a subgenus only, the species is written *Stoekoceros conkingi*, or in one place *S. (Tetrameryx) conkingi*, and a subfamily Stoekocerotinae is proposed (p. 36) to include the group containing *Stoekoceros*. Evidently the subfamily should be Capromerycinae, based on the oldest genus, and in no case, according to the rules, can it be based on a subgenus. It might be possible to argue, perhaps, that in spite of his intention, Friek had in fact raised *Stoekoceros* to generic rank by his mode of citation. Should this view prevail, Stoekocerotinae might be retained.

Another problem relates to the permissible length of generic and subgeneric names. Friek has, for example, a new subgenus *Pseudoparablastomeryx*. I have for many years followed a suggestion made by an author whose name I have forgotten, that such names should never exceed six syllables. There must be a limit somewhere, and perhaps the six-syllable rule would be acceptable, at least for future proposals.

The Number of Discriminable Colours

ALTHOUGH a calculation of the approximate number of discriminable colours must depend upon the individual concerned, 'normal' persons may be expected to furnish data which agree to the correct order of magnitude. The method used here involves the choice of an arbitrary colour solid, the well-known Titchener-Ebbinghaus double pyramid, to which available experimental data are applied with simplifying assumptions, in order that ordinary geometry may be used in the calculations. A straight line connecting the apexes of this double pyramid represents the black-white, or brilliance series; the saturation series is represented by lines running from the central axis to the surface; and the hue series is given by lines on the surface of the figure parallel to the base.

The observations of König¹, ranging from threshold to blinding intensity, give 660 discrete steps as the length of the brilliance axis. Jones², utilizing the measurements of Steindler, Nutting and himself, found 128 just noticeable chromaticity steps in the spectrum. Smith³ obtained 28 hues in the psychological purples. For the total number of hues, equivalent to the perimeter of the base, we have 156. Data for saturation are taken from the incomplete experiments of Geissler⁴, the work being done with coloured papers and covering only certain limited ranges. The results show 90 discrete steps from neutral grey to red. While Geissler did not determine the number of steps to each of the other corners, he measured the relative saturations from which the appropriate data may be computed: yellow, 35; green, 28; and blue, 67.

These values indicate that the base of the pyramid, if drawn to scale, could not be represented by conventional geometry. For the degree of approximation required here we may take arithmetical averages. We find 39 hue steps between each corner of the base and 55 saturation steps from the periphery to central grey. We shall assume that the number of hues, a function of the saturation, decreases linearly from periphery to centre, thus giving 78 hues at mean saturation. The number of colours in the base becomes 4,200. This is not the 'area', but the total

colour sensations, the spacing of which depends upon location. Since König's results are approximately symmetrical, we may use the ordinary formula for the volume of a double pyramid, and thus we obtain for the number of discriminable colours, to two significant figures, the value 9.4×10^4 . If a double cone is chosen, the results will be the same.

An Effect of X-Radiation on the ζ Potential of Colloidal Graphite

IN the course of our attempts to elucidate the nature of the action of X-rays on colloids, we have been investigating the effect of irradiation on the ζ potential of the colloidal particles. The sol selected for the preliminary experiments was an artificial graphite dispersed in conductivity water with the aid of traces of ammonia. This sol is practically homogeneous towards X-radiation, and has a low electrolytic content. It is stable, and the ζ potential of a given stock shows no significant changes over a period of four months. The ζ potential is deduced from measurements on the electrophoretic velocity of the particles. The experimental technique employed in our laboratory has been fully described by Lane and White¹, who have shown that the probable error of a single observation is of the order of 2½ per cent.

Fig. 1.

The nature of the results obtained is indicated, for small doses of radiation, in the accompanying graph (Fig. 1). The ordinates represent the percentage change in ζ potential, the abscissae the corresponding doses measured in röntgens. It will be seen that a significant increase in the negative ζ potential is produced by a dose of only 25 r., but that the effect is not a monotonic function of the dose. The oscillations persist, with undiminished amplitude, but with increasing wave-length, up to doses of 25,000 r. Effects of a similar kind were also obtained with gamma radiation. For one of the sols measured the percentage changes in potential at the first maximum (25 r.), first minimum (85 r.) and second maximum (145 r.) were $+ (7.0 \pm 0.6)$ per cent, $- (6.0 \pm 0.6)$

per cent and $+ (9.6 \pm 1.1)$ per cent respectively. The scatter of the separate observations for a particular dose was, in all cases, consistent with the estimate of the probable error of a single observation given by Lane and White.

The demonstration of a significant physical effect in a stable colloid by X-radiation amounting to no more than 25 röntgens is, so far as we can ascertain, novel: as is also the peculiar relation between effect and dosage. The experiments, in which we have been aided by a grant from the British Empire Cancer Campaign, are being continued.

Determination of Electronic Charge by the Oil Drop Method

We have eliminated the convection current and the effect of the arc and minimized the variation of time of descent of the drops and the greatest common divisor, by using our new oil.

The battery used was two ampere-hour lead cells, highly insulated, giving constant potential with drop of less than two volts per 10,000 volts per five hours. This high potential enabled us to reduce the number of charges on the drop considerably. The water of the bath was constantly circulated and its temperature controlled to within a few thousandths of a degree centigrade for a period of weeks. The condenser plates, having a diameter of 22 cm. and thickness of 2.5 cm., were of stainless steel, optically polished and separated by the quartz prisms. The air used in the tank was dry and free from foreign matters. The timings were recorded on the Société Genevoise printing chronograph, which was controlled every second by the Riefler master clock of the Institute, the variation of which is less than one hundredth of a second per day.

With these precautions and improvements, and further, eliminating the non-spherical drops, we have determined the electronic charge, using Harrington's value for viscosity, and obtained

$$e = (4.806 \pm 3) \times 10^{-10} \text{ e.s.u.}$$

We wish to express our thanks for a financial grant from the Hattori Hokokai.

Temperature Variation of Magnetic Anisotropy of Organic Crystals

As has been shown by Krishnan¹ and his collaborators, the study of the magnetic anisotropy of organic crystals enables us in many cases to determine the orientation of the molecules in the crystal lattice. A natural extension of this important line of work, suggested to me by Sir C. V. Raman, is the investigation of the effect of temperature on magnetic anisotropy, which may be expected to yield valuable information regarding the character of the thermal

motions (for example, oscillations and hindered or free rotations) of the molecules in the crystal lattice and to elucidate the mechanism of fusion.

I have carried out measurements in the case of resorcinol over a range of temperature from 26° C. up to the melting point (110° C.) of the substance. Resorcinol was chosen because the crystal is stable and does not volatilize easily. The structure of the crystal has been studied by Robertson² by X-ray analysis, and the magnetic anisotropy at room temperature has also been determined by K. Lonsdale³. The method described by Krishnan⁴ was adopted for the measurement of anisotropy, a modified technique being employed for fixing the crystal at the end of the quartz fibre and for making the measurements at the higher temperatures.

Fig. 1.

The following experimental procedure was adopted. For any setting of the crystal, the magnetic anisotropy in the plane concerned was first of all determined at room temperature. The crystal was then raised to the desired temperature by electrically heating the surrounding tube, the temperature at the region near the crystal being measured by means of a calibrated thermo-element. The magnetic anisotropy at the high temperature was then measured. The crystal was finally allowed to cool down to room temperature and the anisotropy again measured. It was found that when the high temperature did not exceed 105° C., the initial value of the anisotropy was almost fully restored. In all cases the mean of the initial and the final values of the magnetic anisotropy at room temperature was used in the calculations.

The variation of the magnetic anisotropy with temperature when the crystal is suspended with the *c* axis vertical is shown in Fig. 1. Up to about 15° C. below the melting point, the change of anisotropy is comparatively small. From *b* to *c* on the curve the variation is pronounced. From *c* onwards the transition is very rapid, indicating a state of instability. When the crystal was heated until it began to melt, the anisotropy practically disappeared. It is significant that the effect of temperature becomes prominent only in the vicinity of the melting point.

A determination of the magnetic anisotropy of resorcinol at room temperature gave the values: $\chi_a - \chi_b = 8.13 \times 10^{-4}$, $\chi_a - \chi_c = 13.30 \times 10^{-4}$, $\chi_c - \chi_b = 5.22 \times 10^{-4}$, whence assuming Pascal's value

-67.2×10^{-6} , for the mean susceptibility, we get $\chi_a = -66.2 \times 10^{-6}$, $\chi_b = -74.3 \times 10^{-6}$, $\chi_c = -61.0 \times 10^{-6}$, and $\alpha = 55.9^\circ$, $\beta = 47.0^\circ$, $\gamma = 62.1^\circ$, in satisfactory agreement with the results of K. Lonsdale.

I have also made a preliminary investigation of the magnetic anisotropy of ammonium nitrate at different temperatures up to the melting point of the crystal. The magneto-crystalline data seem to lend support to the findings of X-ray analysis³ in regard to the variation of the crystalline structure of ammonium nitrate with temperature.

The X-Ray Microscope

As I pointed out some time ago¹, a new kind of X-ray spectra can be obtained by focusing the characteristic X-radiation emerging from the surface layer of an object. Instead of the usual spectral lines, these spectra contain a series of monochromatic *spectral images*, each of them showing the distribution of a certain chemical element in the surface layer of the object. Fig. 1 shows a new arrangement of the object, crystal and photographic plate giving a more distinct and even enlarged monochromatic X-ray image. The object *O* is excited to secondary radiation by primary X-rays. The secondary radiation is reflected on the concave side of the cylindrical crystal *K* and collected to the true monochromatic X-ray image *I*. If the dimensions of the object are small compared with the radius *R* of the crystal, it is possible to satisfy the conditions for a *true enlarged image* by adjusting the positions and inclinations of object and photographic plate.

Fig. 1

The test-object for the method was a packet of thin metal foil polished perpendicular to the planes of the different layers. Fig. 2 shows the X-ray photomicrograph of such a test-object (above), with the dimensions of the different layers (below). The X-ray photo-micrograph corresponds to the iron *K α* -radiation, and as this radiation consists of two slightly different wave-lengths, the image of the iron foil appears twice.

By such X-ray photomicrographs chemical analysis for a great number of chemical elements in objects not larger than 10^{-8} c.c. is made possible without dissipating the sample.

A more detailed theory of this X-ray microscope will be published in the *Journal of Scientific Instruments*.

Frictional Torque of an Axial Magnetic Suspension

A VERTICAL needle of iron suspended *in vacuo* by the co-axial field of a solenoid theoretically may have infinitesimal frictional torque against axial rotation. The purpose of the present note is to report an observed value of this frictional torque.

The arrangement used is a modification of that previously reported by one of us¹. A solenoid carrying a steady direct current produces a magnetic field sufficiently strong to support a large fraction of the weight of the needle. A vane mounted on the needle controls the amount of light striking a photo-cell. The current from this cell is amplified and fed to a second lifting solenoid. Thus the needle is automatically maintained at a pre-determined height. Vertical oscillations about this position were damped out by using a large resistance in, and capacitance across, the power supply for the amplifier output tube².

For this experiment the vane was a solid aluminum

alloy disk, 15 mm. in diameter and 5 mm. thick, mounted co-axially with the needle. The entire unit had a mass and moment of inertia of about 6 gm. and 0.8 gm. cm.² respectively. It was spun *in vacuo* by the action of the field of a small bar magnet mounted horizontally on an air-driven turbine¹ spinning below the disk at about 1,500 rev./sec.

The rotor was speeded up to about 1,200 rev./sec. Its action was such as to indicate that small or large rotors probably can be taken up to their bursting speeds with macroscopic stability, and that many types of drive may be used.

Damping observations were carried out at speeds in the neighbourhood of 600 rev./sec. with the driving magnet removed. Under these conditions, one encounters a frictional torque due to residual gases, and three torques of electromagnetic origin due to misalignment and the earth's magnetic field. In this preliminary work the residual gas pressure was estimated to be of the order of magnitude of 10^{-3} mm. mercury, alignment was done roughly, and no attempt

was made to neutralize the earth's field. However, the observed deceleration at the above speed was about 2×10^{-3} rev./sec.², corresponding to a frictional torque of about 10^{-3} dyne cm.

It is believed that this device offers possibilities in experiments in which it is necessary to suspend rotatable systems under a variety of conditions. The low frictional torque exhibited suggests its use in experiments in which this property is useful directly, or indirectly as in the attainment of relatively constant rotational speeds for use in velocity of light determinations, etc.

Points from Foregoing Letters

Measurements of cosmic ray intensities at various atmospheric heights at Madras, India and San Antonio, Texas, indicate, according to Prof. I. S. Bowen, Prof. R. A. Millikan and Dr. H. V. Neher, that the incident cosmic rays produce their maximum ionisation before they penetrate more than one tenth of the atmosphere. The authors deduce, from the absorption coefficient down to sea-level, that the particles in the cosmic rays are predominately positive electrons, not protons.

Prof. G. Lemaitre points out that the discrepancy in the position of the magnetic centre of the earth, as determined from magnetic measurements and as calculated (from the variations in the intensity of cosmic rays along the magnetic equator), is considerably reduced if one takes into consideration that the cosmic rays consist mainly of positively charged particles.

A photomicrograph of crystals of lysozyme, a protein occurring in the nasal mucosa, capable of lysing certain bacteria, is submitted by E. P. Abraham and Prof. R. Robinson. From the ultra-violet absorption spectrum, the presence of 4.4 per cent of tyrosine and 2.2 per cent of tryptophane is deduced.

Dr. T. Iredale and A. Maccoll find that ethylene bromide ($C_2H_4Br_2$) decomposes at 340° – 370° in a pyrex vessel into vinyl bromide (C_2H_3Br) and hydrogen bromide. This reaction is heterogeneous. No decomposition into ethylene and bromine was observed. The authors suggest that the *trans* form of ethylene bromide is the more stable at high temperatures.

Addition of co-carboxylase to acetone-treated lactic acid bacteria (which had thereby lost the ability to dehydrogenate pyruvic acid) restores their power of dehydrogenation, or oxidation, according to F. Lipmann. The presence of phosphate is essential to the reaction.

H. J. Almquist reports that vitamin K, which preserves normal blood-clotting in chicks, has been obtained in crystalline form.

Dr. H. L. Pearce finds that hetero-auxin sprayed on to the shoots of plants of the broad bean grown in water culture causes swelling of the stem, epinasty of the leaves, and inhibition of the terminal bud,

while the form of the root growth is unaffected. Approximately the same amount added to the culture solution retards the growth in length of the roots, and accelerates their growth in thickness, while the shoots, although slightly retarded, remain normal in appearance.

Experiments with cuttings of *Leptospermum scoparium* and of *Picea repens*, confirming the root-stimulating properties of skatole, are reported by L. G. G. Warne and A. A. Jackson.

C. A. Wingfield has compared the oxygen consumption of normal and gill-less nymphs of a mayfly at various oxygen concentrations. It appears that the gills play little or no part in respiration at high oxygen concentrations, and only aid the oxygen consumption when the oxygen content of the water is reduced to a low value.

Using the Titchener-Ebbinghaus colour pyramid as the psychological colour solid, Dr. G. B. Welch calculates the number of discriminable colours to be of the order of 940,000.

A curve submitted by J. A. Crowther and H. Liebmans shows that when a colloidal dispersion of graphite is treated with increasing doses of X-rays, its zeta-potential (measured by the velocity of the suspended particles in an electric field) alternately increases and decreases.

A new determination of the charge of an electron by Y. Ishida, I. Fukushima and T. Suetsugu, with additional precautions and improvements, gives a value of $e = (4.806 \pm 3) \times 10^{-10}$ e.s.u.

An X-ray microscope by means of which a true enlarged image of chemically different layers, about 1/100th millimetre apart, was obtained, is described by Dr. L. V. Hamos. It depends on the focusing of the characteristic secondary radiation emitted from a surface layer of an object subjected to primary X-ray irradiation.

Drs. F. T. Holmes and J. W. Beams describe a macroscopically stable axial magnetic suspension which has a very small frictional torque. A six gram rotor when coasting at 600 r.p.s. required about eight minutes to lose one revolution per second.

Research Items

Delaware Ceremonies and Dances

MR. FRANK G. SPECK, who has made a detailed study of the Big House ceremonial of the Delaware, or Lenape Nation, now turns his attention to other ceremonies of no less importance, but of lesser duration (*Mem. Amer. Phil. Soc.*, Philadelphia, 7; 1937). The Big House ceremonial lasts for twelve consecutive nights, and is the periodical communal ceremony, which is the consummation of Delaware religious fervour. It expresses their attitude towards the benign Supreme Being. In their annual cycle, however, there is a number of other rites and ceremonies, in which they enter into relation with other spiritual beings, from whom, for the most part, evil is anticipated. Even though the Lenape have been removed from their original home in Pennsylvania and New Jersey to Oklahoma, these ancient rites have continued in practice down to the present day. It is probable that they are of a more ancient origin than the Big House ceremony. Some of them, as for example the Grease Drinking ceremony and the Doll dance, are family properties handed down as obligations to the tribe within the family group. The ceremonies are supposed to have originated through the mythical association of family ancestors with supernatural agencies. This is usually explained in a mythical narrative. Their purpose is to satisfy an offended spiritual force and to prevent a recurrence of the original misfortune avoided by the rite. The group performing the ceremony gains an added blessing in some form, such as an augmentation of crops. There are various officials of the ceremonial, of whom the chief is a master of ceremonies. The performance usually takes place at night. In addition to the description of the ceremonies, an account is given of the Delaware form of the dance taking place when the bones of the dead, from which the flesh has been stripped, are buried.

Early Peruvian Textiles

A LARGE number of specimens of textiles from early sites in the Nasca valley, Peru, numbering one hundred and sixty in all, collected by Prof. A. L. Kroeber in 1928, on behalf of the Field Museum, Chicago, have been described by Dr. Lila M. O'Neale, associate curator of textiles in the Museum of Anthropology at the University of California (*Anthropology: Memoirs*, Field Museum, Chicago, 2, 3). In an introductory note, Prof. Kroeber points out that Early Nasca textiles were not previously well known, and in fact were scarcely recognized; but the present material affords adequate data for satisfactory study, owing to the fact that he was able to establish the archaeological associations of his specimens. It has now been shown by Dr. Tello's archaeological investigations at Paracas that the finely embroidered polychrome shawls and garments, at first identified as Ica and then as Nasca, are now to be associated with Paracas. The stylistic relation between Early Nasca pottery designs and those of Paracas textiles is so close as to leave little doubt of a common origin, the pottery probably being the earlier. The Early Nasca textile art discovered in association with Early Nasca pottery is largely decorative and tends to the geometrical, while its representations of naturalistic

impulses are relatively undeveloped. Nasca pottery and Paracas fabrics go together, while Nasca fabrics and Paracas pottery are alike in not attempting naturalistic representation. When the Early Nasca peoples wanted a picture on cloth, they painted it on. One example of this was found, duplicating in design a well-known Early Nasca pottery type, birds in attitude and placement in the design being identical with birds painted on double-spouted jars. The most striking feature of the Early Nasca textiles is their range of colours. They show a total of 190 hues by comparison with a colour scale, the majority to be described in terms of red, orange and yellow. The material used is a finely spun cotton yarn. Five of the eight standard weaves known to modern weaving were known to the Early Nasca, and in addition they did wrapped weaving, as in basketry.

Problems of Population Density

THE biological principles affecting populations are discussed by Raymond Pearl (*Amer. Naturalist*, 71, 50), with references to experimental work on animal populations. He points out that the fundamental underlying principles are the same in man and in other animals; and that population growth or decrease has had an important effect in shaping political conduct and national policies, human populations differing in size, growth and quality. He is inclined to conclude that the human population of the earth grew very slowly until about three centuries ago, and then, as a result of scientific discoveries, took a great spurt and so increased from some 445 millions to more than 2,000 millions, or 40 persons per square mile of the earth's land surface. He regards this cycle of population growth as about two-thirds completed, and compares it with the cycles of lessening population. He interprets these cycles as beginning with a period in which the population remains relatively constant, followed by abatement of some of the natural checks, which leads to rapid increase. Population density finally reaches a point where new stimuli, reinforced by gregariousness, lead to migratory movements and ultimate destruction of masses of individuals. In the same journal, Dr. Thomas Park discusses in detail the recent experimental work on insect populations, with special reference to density effects.

Laboratory Diagnosis of Psittacosis

PSITTACOSIS or 'parrot' fever is a virus disease of cage birds, and is communicable to man, in whom it causes a serious and often fatal malady. This disease was comparatively prevalent in Great Britain and in the United States some years ago, and was of sufficient importance for the Ministry of Health to issue a memorandum, with recommendations upon its diagnosis and prevention. As a result of recent investigations, it has become possible to give more precise indications for the detection of the disease in man and in animals, and the Ministry of Health has published a report containing details of the technique of laboratory diagnosis (*Laboratory Diagnosis of Psittacosis*. Reps. on Pub. Health and Med. Subjects, No. 80. London: H.M. Stationery Office. 6d. net). The examination of suspected birds and

of suspected human beings is described. The staining of smears of material for virus bodies, and the microscopic appearance of the virus are also described, and the appearances found are illustrated in an excellent coloured plate.

Feeding of *Chirocephalus*

SIR E. RAY LANKESTER in his essay on *Apus* (1881) first used the term 'gnathopod' for the proximal endite of the trunk limb, stating that it was a jaw-process which clearly had the function of assisting, by means of apposition to its fellows on the opposite side, in seizing and moving particles which may be introduced into the mouth. A. G. Lowndes, in his recent paper on *Chirocephalus* (The Term "Gnathopod" (Lankester). *Proc. Zool. Soc. Lond.*, B, Part 1; 1937), is in complete agreement with Lankester, and concludes from direct observations and by the use of his strobographic method, described in *NATURE* (1935, 1006; 1935) that the setules of the basal endites can and do act in apposition while the limbs are working normally. He finds, however, that they do not do so always, and this, he believes, confirms his previous observation that the endites are under both muscular and nervous control and that one need not look upon the passage of food particles towards the mouth as being in any way automatic. Mr. Lowndes and his pupils have examined hundreds of specimens of *Chirocephalus* for gut contents, and find that the food consists almost entirely of quite coarse particles, such as remains of vascular bundles of leaves, etc., which are to be found at the bottom of most ponds. Other detritus such as algal filaments, leaves of moss, and dead Entomostraca are also found in the gut.

New Porcellanids and Pinnotherids

UNDER the title "Porcellanids and Pinnotherids from Tropical North American Waters", Mr. Steve A. Glassel describes several interesting forms, mostly collected by himself (*Trans. San Diego Soc. Nat. Hist.*, 8, No. 21; 1936) from the west coast of Mexico and from the Gulf of California. Four new species of *Petrolisthes*, three of *Piscesoma*, two of *Pachycheles* and three of *Porcellana* are included. The new genus *Orthochela* in the Porcellanids is created for another new species, *O. pumila*, which is very peculiar in the shape of its carapace, resembling *Uroptychus* in the family Galatheidæ. This crab is figured and also the outer maxillipedes of the three new species of Pinnotherids, *Fabia unguiculata*, *Disceodactylus zantusi* and *Pinnixia richardsoni*. Otherwise the paper is not illustrated.

Locust Control

THE Committee on Locust Control of the Economic Advisory Council has issued a fifth survey of the locust outbreak in Africa and Western Asia. The latest of these surveys deals with the situation in 1935 and has been prepared by Dr. B. P. Uvarov, in collaboration with Miss W. Milnthorpe, of the Imperial Institute of Entomology. It appears that the outbreak of the three species of locusts, which have brought about so much damage during the past eleven years, is subsiding. At the same time it is pointed out that no relaxation in the campaign of locust investigation would be justified on this account. The desert locust, for the first time since 1926, had not invaded North Africa. The appearance of a swarm in May, 1936, in the Darfur province of the

Anglo-Egyptian Sudan is disquieting, since its origin must be in an unexplored coastal area of the Red Sea. The possibility that it may sooner or later develop into a new invasion needs to be kept in mind. As regards the African migratory locust, it is now known that the outbreak centres are in the Middle Niger region. It is believed that this area is the only real danger spot in the whole continent of Africa in so far as this species is concerned. Practical measures are being planned for the permanent supervision of that outbreak area. With the red locust, heavy mortality has been caused by the fungal disease *Empusa grylli* among both the hoppers and winged forms. Viewed generally, the outbreak of this species is on the decline; but swarms are likely to be still produced for some years to come.

Mutation in Tobacco Virus

MUTATIONS in viruses are the subject of a paper by Dr. H. H. McKinney (*J. Hered.*, 28, No. 2), who cites experimental work, especially with mosaics of tobacco. While these viruses tend to remain true to type over long periods, yet they give rise in local zones of the infected plant to aberrant viruses which when isolated induce distinct symptoms. Some of these aberrant viruses in turn give rise to others. This is interpreted as a mutational phenomenon. Such mutants differ in the changes they produce in the chlorophyll mechanism of the leaf, some producing no disturbance, others a slight disturbance (light green mottling), others a yellowish-green, yellow or even almost white colour. Temperature has an important effect on these disturbances. Nearly a hundred mutants have been isolated from the common mosaic, but the number of distinct types is uncertain. Sub-mutants are also produced, the whole system of types tending to show certain relationships. The generation of these bodies is believed to be different from that of an enzyme from its precursor. The primary virus and its mutants are regarded as a series of closely related compounds which function essentially as genes.

A Rice Fermentation

ALCOHOLIC fermentations fall into three groups: (1) the direct inoculation of the fruit juice by yeasts as in wine production; (2) the fermentation of a grain extract after pretreatment as the malted grain in beer; and (3) the reinoculation of a partially cooked plant material. Rice as a source of alcohol has had to be approached from this third angle by K. Rami Reddi and Dr. V. Subrahmanyam, of the Indian Institute of Science, Bangalore, who have published a most interesting paper upon 'Sonti' fermentation (*Trans. Nat. Inst. Sci., India*, 1, No. 11, 1937), which describes and analyses traditional methods of rice fermentation handed down from father to son, often as secret customs in small village communities, and then gives a preliminary estimate of their biochemical and biological basis. The 'Sonti' fermentation is practised in certain districts of the Madras Presidency. The main organism associated with the process appears to be a hitherto undescribed species of *Rhizopus* provisionally named *Rhizopus Sontii*. It is allied to *R. cambodia*, but its physiological activities are more pronounced. Indeed *R. Sontii* may have a practical future before it as it liquifies and saccharifies cooked rice more rapidly than other well-known organisms, including *Aspergillus oryzae*. This paper is fascinating in its linkage of tradition

with modern problems of biochemistry and mycology, and it shows the great possibilities of advance in standards of nutrition as the result of scientific study of methods of food preparations that are acceptable to a conservative native population. Studies of the species of *Rhizopus* isolated from Chinese yeast cakes such as are used in brewing alcohol from cereal grains in China, Manchoukou and Korea are also being extensively carried out by M. Yamazaki, professor of zymology (*Bull. Utsunomiya Agric. Coll.*, A, 2, No. 6, 1937).

Cyclones in the South Indian Ocean

MISCELLANEOUS PUBLICATIONS of the Royal Alfred Observatory, Mauritius, have in recent years included an annual publication in which an account is given of all the tropical cyclones that have been noted in the last cyclone season in the South Indian Ocean from Coos Keeling Island across to Madagascar and the adjacent coast of South Africa. Publication No. 16, by N. R. McCurdy, director of the Observatory, which is the seventh of its kind, covers the season 1933-34. The number of depressions of sufficient intensity to be classed as tropical cyclones or hurricanes in that season was eight, which is about the average number; but the weather was more than usually disturbed during the hurricane season, and seven other disturbances are referred to briefly. It is said to have become increasingly evident in recent years with improvements in the synoptic charts, that the formation of cyclones is closely related to the periodic invasions into low latitudes of the cooler air associated with subtropical high-pressure systems. These systems usually move north-eastwards from South Africa but sometimes northwards. In the season under discussion, areas of disturbed weather always developed at the northern limit of the high-pressure wave when the latter was of appreciable intensity, and these sometimes led to the development of a tropical cyclone. Observations with pilot balloons at Mauritius showed that this happened whenever the east or south-east trade winds of the 'high' extended up to 5,000 metres. This is held to be a result of importance in forecasting, in the absence of enough observations from the Indian Ocean to the north of Mauritius to permit of the approach of cyclones to be studied for some days before their arrival near to or over the island itself. None of the storms of this season appears to have been of very outstanding intensity, but some showed interesting features; for example, that of January 26-February 2, which was deflected from its course by the high land of Mauritius, although the highest 'peak' of the island has only an elevation of about 2,700 ft. Another storm in March was broken up into two centres by its encounter with Madagascar, and soon died out.

Absolute Measurements of Sound Intensity

E. N. DA C. ANDRADE and R. C. Parker (*Proc. Roy. Soc.*, A, 159, 507) have measured the amplitude of vibration of smoke particles suspended in a vibrating air column. A theoretical calculation shows that, in the case of fine particles (radius about 0.03μ), this amplitude is very nearly indeed that of the air itself, and this result is confirmed by the fact that particles of different size in the same air column show the same amplitude of motion. The particles were seen and photographed by scattered light: they appeared as well-defined short lines of light. The

apparatus was kept at a constant temperature both to reduce convection and to give generally consistent operation. When the apparatus had been calibrated, it was used to determine the minimum amplitude audible to a number of observers. The end of the tube was allowed to radiate into the open air, and the intensity varied while the observer indicated when the sound passed above and below his threshold of hearing. The observed minimum intensities for audibility were very similar for a number of observers. They corresponded to a pressure variation of 1.2×10^{-3} dynes/cm.² R.M.S. at 410 cycles and 0.9×10^{-3} dynes/cm.² R.M.S. at 646 cycles. The corresponding energy fluxes are 8.4×10^{-8} erg./cm.² sec. and 2.1 erg./cm.² sec.

Lead Borates

A KNOWLEDGE of the system $PbO-B_2O_3$ is of importance in the manufacture of ceramic glazes and glasses, and a study by well-known methods involving quenching and petrographic examination has been made by R. F. Geller and E. N. Bunting (*J. Res. Nat. Bur. Stand.*, 18, 585; 1937). Four compounds were characterized, namely, $4PbO.B_2O_3$, occurring in two forms and melting congruently at 585° ; $2PbO.B_2O_3$, occurring in two forms and melting incongruently at 497° ; $5PbO.4B_2O_3$, melting incongruently at 548° ; and $PbO.2B_2O_3$, melting congruently at 788° . No evidence of compounds richer in B_2O_3 was obtained, although these have previously been reported. Particular attention was given to the proof that the compound $5PbO.4B_2O_3$ is not the metaborate ($PbO.B_2O_3$). The eutectic of lowest melting point, 493° , was composed of 88 per cent PbO and 12 per cent B_2O_3 . The report also gives the indices of refraction and optical characters of the compounds, and the indices of refraction, coefficients of expansion and softening points of some lead borate glasses.

Isotopes of Potassium

THE abundance ratio for the two principal isotopes of potassium, K^{39}/K^{41} (the exceedingly rare isotope K^{41} is responsible for part and possibly all the radioactivity) in various animal tissues has been measured by J. H. Yoe and R. T. Hall (*J. Amer. Chem. Soc.*, 59, 869; 1937) by means of the mass spectrograph. Any process which concentrates K^{41} will doubtless concentrate K^{39} , and as speculations have been made on the possible biological importance of potassium, owing to its radioactivity, it was of interest to see whether the abundance ratio varied in different tissues. The results showed that the ratio for most organs is close to the value found for most plants and minerals and for ocean water. A few tissues, such as the lining of the auricle and the lining of the small intestine, appear to possess an abnormally high concentration of K^{39} , whilst bone marrow is abnormally high in K^{41} . The atomic weight of potassium was calculated, with the most probable value of the packing fraction and the conversion factor; for most tissues it is 39.094. Since all deviations from this normal value are small, it does not seem probable that potassium in animal tissue could be distinguished from mineral potassium by radioactive measurements as has been suggested by some investigators. The results with bone marrow indicate a possible relationship between the abundance ratio and the age of the animal, and hence with the development of embryonic cells within the organism.

The International Congress of Agriculture

MEETING AT THE HAGUE

THE seventeenth International Congress of Agriculture was held at The Hague on June 16-24. Great Britain was officially represented for the first time for many years, though at recent congresses members of the Women's Institutes and the Horace Plunkett Foundation have been present. There is always a tendency in Great Britain to regard international congresses, other than those of specialists, as somewhat in the nature of 'joy-rides'. Languages undoubtedly present a difficulty that weighs more upon our people than upon Continentals, and this applies more particularly to those informal discussions and personal contacts from which those who participate in the Congress gain most.

The abstention of British representatives of agriculture from this Congress has most probably been due to the feeling that their industry is fundamentally different from the European system, in which peasant farming predominates. However, nowadays nearly all nations have embarked upon policies of control and regulated marketing, about which there is much to be heard from the Continental experiments, which aim like our own at the safeguarding of an industry ill-adapted to hold its own under modern conditions. From every nation one hears the same tale of low prices, of the inability of the farmer to hold his own against the trader or to get his products to the consumer at prices commensurate with those which he receives, and of the drift of men from the land. A 'Green International' is not possible, so diverse are the interests and the organization of the land and the farmers in different countries, but one's domestic policy is more likely to be successful if it is informed of what is going on elsewhere.

From the technical side, Holland is the country most worthy of study by the British farmer; its agriculture is highly accomplished and works under conditions of mixed capitalist exploitation and small holders, analogous to our own. Livestock bulk large in the system and the organization either of registration, disease prevention, advice, even of shows, affords us much to think about. The production of sugar from beet is higher in the Netherlands than in any other country—for the years 1926-29, 4,000 lb. per acre as against 2,500 lb. in Great Britain. Vegetable growing exhibits an exceptionally high general level of efficiency, even if some of our experts need fear no comparison.

It was therefore somewhat of a lost opportunity that British representation at the Hague Congress, except in the women's section, was still so limited. The formal opening was attended by H.R.H. Prince Bernhard and a representative of the Queen, the Prime Minister of the Netherlands and the Minister of Agriculture, the Minister of Agriculture of Italy, the president and secretary general of the International Institute of Agriculture at Rome, and representatives of forty nations in all. In welcoming the Congress, M. Colijn, Prime Minister, made a courageous speech on the necessity of breaking down the trade barriers between nations which have so often been set up in response to the pressure of particular interests. This was followed by a remarkable

demonstration, at which the representatives of one country after another affirmed that the maintenance of peace was the prime necessity for the maintenance of agriculture and indeed of the world's civilization.

Then, as is customary, the Congress resolved itself into its various committees. The first and third sections, dealing with agrarian policy and co-operation respectively, bore perhaps little upon British conditions, though the discussion on the international market for butter was of interest to the Dominions. The second section discussed education and propaganda, and the chief point raised was the importance of economic studies in the agricultural colleges as a means of preparing trustworthy leaders of opinion in these times when so much legislation affecting agriculture is being proposed. The fourth section, on plant production, produced discussions on the improvement of protein yield from light soils and on vernalization, with some reference to the recent clash between the advocates of vernalization and the geneticists in Russia. Of great interest was the account of recent legislation in Germany to restrict the number of varieties of farm crops that can be offered for sale, a restriction dependent upon an organization for testing the productivity of the immense number of varieties that are more or less in cultivation. It was reported, for example, that from the 348 varieties of wheat formerly to be found in Germany, only 11 may now be sold, with a further 34 under trial. The vexed question of assuring to the breeder of a new variety protection analogous to that of a patent was discussed at some length. If legislative control is obtained of the varieties that may be offered for sale, it is possible to secure royalties on the stocks multiplied from the original which has been duly characterized and registered, but while something is thus practicable internally, the situation is complicated by the existence of international trade and the lack of any general system of testing and registration. In the section on livestock production, discussion chiefly turned on the role of vitamins and mineral accessories, and several of the papers presented merit careful consideration.

In the women's section the chief report had been prepared by Mrs. Haldane, on public health regulations in English villages. The role of the woman in agriculture is obviously much larger in the European countries than in Great Britain, owing to the predominance of peasant farming; hence the greater attention that is being paid to instruction in the domestic economy of the farm.

The Congress was admirably prepared and organized; before the meetings copies were available in French of the reports and of the main communications. It might, however, well be laid down that a speaker whose paper has been printed should not read it at length, particularly in a language in which he is not at home; in some sections the time for discussion was seriously curtailed by this.

The Congress was followed by excursions to the reclamation works of the Zuider Zee, the experiment station at Wageningen, and to farms representative of the milk production and market gardening industries.

The National Physical Laboratory

INSPECTION BY THE GENERAL BOARD

THE annual inspection of the work in progress at the National Physical Laboratory was made on June 22, by the General Board and also by about two thousand visitors, who were received in the High Voltage Laboratory by Sir William Bragg, president of the Royal Society, chairman of the Board, Lord Rayleigh, chairman of the Executive Committee, and Sir Frank Smith, director of the Laboratory. Amongst the numerous exhibits in the eight departments of the Laboratory the following may be mentioned.

A comprehensive investigation into the thermal properties of a number of alloy steels is being made in the Physics Department up to temperatures of the order of 800°C . The thermal and electrical conductivity, specific heat, latent heat at the transformation points, and thermal expansion, are measured *in vacuo*. The specific and latent heats are determined by measuring the rate of rise of temperature of a hollow cylindrical specimen in which an electric heater is embedded. Loss of heat by radiation is avoided by surrounding the specimen with a jacket of low thermal capacity, which can be adjusted always to the same temperature as the specimen. The thermal conductivities of a large variety of materials are also measured in this section, the method generally employed consisting in the determination of the electrical energy required to maintain a known difference of temperature across a specimen of slab or cylindrical form, lateral flow of heat either being annulled by some form of guard system or else determined by a separate experiment.

In another building the apparatus used for the accurate realization of various points on the International Temperature Scale was shown, and the routine testing of various types of thermometers was demonstrated. It should be mentioned here that approximately half a million clinical thermometers have been tested at the Laboratory during the last year.

The radiological work done at the Laboratory can be divided into two sections, one devoted to the precise measurement of the properties and intensities of X-rays and gamma rays and the other to the application of radiography and diffraction methods to the study of the structure of materials. This latter has now become a valuable experimental tool, and typical results obtained by it on electro-deposited, heat-treated and strained metals, tooth-enamel and dentine were shown. A considerable amount of radium has been tested lately, and a valve amplifier apparatus for facilitating this work was demonstrated. The lead equivalents of various building materials to X-rays of different hardness have also been investigated, and the superior performance of barium concrete in this respect was illustrated.

A popular exhibit in the acoustics laboratory—which is at present in process of enlargement—was designed to test the efficacy of various anti-drumming treatments applied to metal panels representative of the bodywork of vehicles. The panel under test is held in a rigid square frame which is attached to a moving-coil loud-speaker movement at each corner

and thereby driven at any desired frequency. The acoustic output is measured over a range of frequencies. The measurement of the absorption coefficient of sheet material was also demonstrated in the reverberation room, and a portable instrument for the measurement of noise, in which the peculiarities of the average human ear in this respect have been copied, was shown.

In the Optics Division, apparatus for measuring the intensity-response function of thermopiles and also the time-constant of this response was demonstrated. In the latter, the thermopile is connected to a condenser which is discharged through a ballistic galvanometer by an adjustable time-switch. Amongst the numerous exhibits here devoted to the measurement of colour a spectrophotometer for opaque surfaces was noted. The feeble intensity available from such a surface is counteracted by using a zonal concave mirror which focuses the light received from the specimen on to a photo-electric cell.

The Electrical Standards Division is now in a strong position with regard to the absolute determination of the ohm, inasmuch as the value finally obtained by the A.C. method devised by Albert Campbell has been found to agree to within 1 part in 100,000 with that obtained by the Lorenz machine. The apparatus used in these refined measurements was exhibited and the precautions necessary to attain the required accuracy were illustrated. Amongst other exhibits in this section was a simple form of apparatus for calibrating audio-frequency oscillators, using 50-cycle A.C. mains as a standard. The 50-cycle wave-form is distorted by passage through a metal rectifier and then mixed in suitable proportions with the oscillator output. The resulting combination is passed through a telephone in series with another metal rectifier, and integral multiples of the mains frequency are revealed by the presence of beats. A new type of quartz ring oscillator which will form the principal unit in a standard clock for the Royal Observatory, Greenwich, was also shown, together with the quartz bars used in a recent experiment, which showed that the frequency of vibration of these bars remains constant to ± 4 parts in 10^{11} irrespective of their orientation in a horizontal plane. This has been cited as being the highest precision ever achieved in a physical measurement.

In the Electrotechnics Building, the standard apparatus for the routine testing of alternating and direct current meters of all kinds was shown. The functioning of the thyatron stroboscope recently developed was illustrated by cathode ray oscillograms of the current in various parts of the operating circuit, and the results of a comprehensive theoretical and experimental investigation into the eddy-current losses in square-section alternating current conductors were also shown here.

The work in the High Voltage Laboratory is mainly carried out with impulsive voltages, and cathode ray oscillograms illustrating the work recently done were exhibited. In addition, the testing of a pin insulator with simultaneous alternating and impulsive voltages

was demonstrated, and the relation between the phase of the impulse and the probability of an ensuing power arc illustrated. The demonstration of high voltage sparks proved, as usual, to be a very popular exhibit.

In the Photometry Building, an exhibit which attracted attention was concerned with street lighting. A cinema film was prepared from a series of photographs of a night street scene and the projected image viewed from a definite position. On recognising the change from one scene to another, the observer presses a key which operates the shutter of a camera, thereby recording the instantaneous position of the film, and hence the delay in recognition. This has been carried out with various sources of illumination in order to find out if any of them have advantages from this point of view. In this building there were also exhibits illustrating the routine testing of electric lamps, maintenance of photometric standards, and other illumination research. The photo-electric spectrophotometer recently developed was shown in operation: this has materially reduced the time and tedium involved in visual measurements of this nature.

In the Radio Department the chief exhibits, which were shown on the same occasion last year, were a direction-finding radio receiver for use on wavelengths between 8 and 10 metres, a self-checking, direct-reading, frequency-measuring equipment for the range 1-70 megacycles per second, which is based on a standard 1,000-cycle tuning fork, and a number of coils and condensers of very low or adjustable temperature-coefficients of reactance.

The synchronization of a pulse transmitter and receiver, such as are used in the ionosphere research of the Radio Department, where the frequency of the exploring waves may be varied over the range 1-20 megacycles per second, has been effected automatically. The receiver is tuned by means of a small reversible electric motor, suitably geared down, which is controlled, through a system of relays, by currents which depend on the difference in frequency between the transmission and the frequency-change oscillator of the receiver.

An interferometer for routine measurements of block gauges which was exhibited in the Metrology Department has very materially decreased the time occupied by such tests. A series of gauges is wrung radially on to a circular lapped plate which is rotated so that each is viewed successively in light of four monochromatic radiations from a cadmium lamp. By estimating to 1/10th of a fringe for each radiation, the amount by which the path-difference between light reflected from the surfaces of the gauge and the plate differs from an integral number of wave-lengths, and knowing the approximate thickness of the gauge, the true thickness may be determined rapidly and without ambiguity. Amongst the new exhibits in this Department was a comparator sensitive to a millionth of an inch, and a circular dividing table reading to 1 second and accurate to 5 seconds of arc, in which the driving mechanism and the reading mechanism are entirely separate, so that the latter is not subject to wear.

An appliance for measuring the drunkenness (that is, departure from a true helix) of screw threads was shown. A pair of round-nosed feelers attached to a floating carriage register in the vee-groove of the screw at opposite ends of a diameter. Rotation of the screw produces axial movement of the feelers, and any inequalities in the movements of the two feelers is revealed on a dial gauge capable of detecting

errors as small as 0.00005 inch. A horizontal projection machine has just been completed. By using suitable lenses, plate gauges up to 3 inches in length can be projected as a whole to a magnification of 25, the maximum error over any part of this field not exceeding 0.0002 inch, whilst the threads of screw gauges up to 8 inches in diameter, and the teeth of large gear-cutting hobs, can be examined at a magnification of 50. An experimental machine for testing the wearing qualities of gauge steels consists of a lapping table on which three ring-shaped specimens rest. The table and the specimens all rotate slowly about their own axes, thereby reproducing a lapping operation.

The combined fatigue testing machine developed in the Engineering Department was in operation on specimens of cast material for use as crankshafts. The high resistance to fatigue of these materials has emerged from the results so far obtained, and a law has been devised determining the behaviour of cast materials under conditions of combined bending and torsional fatigue stresses. Another exhibit of interest showed the results of fatigue tests under corrosive conditions, and the effect of using protective coatings to combat the deleterious effects thereby obtained on a number of steels. Amongst the exhibits connected with problems of lubrication, the influence of small quantities of water on the lubricating value of a motor-car oil was shown. In a journal-bearing machine, a reduction of seizing temperature from 200° C. to 140° C., and an increase of about 40 per cent in the minimum friction, was obtained, with only 0.05 per cent of water.

In the Metallurgy Department the development of magnesium alloys has continued, and data showing the valuable properties possessed by certain alloys containing aluminium and cerium were illustrated. In the rolling mill, the technique of working these alloys was demonstrated, and some very clean examples of forged and machined work were exhibited. A careful exploration of the delta region of the iron-carbon system has recently been made, using materials of the highest purity *in vacuo*. The results were exhibited in the form of the constitution diagram of this particular region of the iron-carbon system. The iron used in this and other researches is prepared in the Department by reduction of ferric oxide in hydrogen. The vacuum fusion method of determining the oxygen content of steels has been improved in reliability by the removal of gases from the apparatus at 2,200° C., thereby reducing both the correction to be applied and the time taken to carry out a test. The main results of the work which has been done on dental alloys for several years were summed up in a model, which shows the relation between the composition of the alloy and its volume change during setting. The narrow limits within which a satisfactory alloy lies were thus well illustrated. Experiments have been made in this Department on the diffusion of gases through wood. With hydrogen diffusing across the grain, it has been found that the rates vary by as much as 2,500 to 1, depending on the variety of wood under test.

The electron microscope is being developed as an experimental tool, and a magnified image of a very fine wire gauge was exhibited to show some of the possibilities of this instrument.

In the Aerodynamics Department the pitot traverse method of measuring aerofoil drag appears to be now more widely used, and satisfactory agreement has been obtained between this and balance measurements. The drags of a number of aerofoils

with various surface finishes have been measured in the compressed air tunnel up to a Reynolds number of 24 millions. Similar experiments on a thin aluminium plate with suitably shaped leading and trailing edges have given very good agreement with the theoretical curve for turbulent flow over a flat plate except at low Reynolds numbers, where the experimental curve tends to fall to the theoretical curve for laminar flow. Two other exhibits in this Department were devoted to the investigation of the transition from laminar to turbulent flow along the boundary of an aerofoil, one employing a visual—or photographic—method, and the other a hot-wire method of detection.

In the large 'duplex' wind tunnel the effect of the slipstream from the propellers of a model monoplane on the stability of the model was being studied, the propellers being driven by an internal electric motor. Another exhibit of interest here was concerned with the problem of wing flutter. The aerodynamic forces acting on a wing section subjected to a sinusoidal pitching motion are measured by the aid of a magnetostriction stress recorder. The high-speed tunnel, which operates by induction from the exhaust from the compressed air tunnel, has been employed in the investigation of the behaviour of aerofoils up to speeds of more than 600 miles per hour, where the effects of the compressibility of air attain a predominating importance.

Experiments on the improvement of ships' lifeboats enabling them to avoid shipping seas in rough water were in progress in the William Froude Laboratory, and the results obtained with a model have been confirmed by full-scale trials of a lifeboat of the best design. Tests were also being made in the new tank on a model propeller partially immersed in water, as for a ship in ballast condition. Automatic records of thrust, torque, revolutions, etc., are made at different immersions. By means of a stroboscope, the action of the blades upon the water during emersion and submersion is observed. It should be noted that during 1936, 88 ship designs were tested in this Laboratory, representing 80 per cent of the merchant shipping listed as "under construction" in Great Britain.

University Events

CAMBRIDGE.—Dr. H. J. Bhabha, of Gonville and Caius College, has been awarded an 1851 Exhibition studentship.

The General Board recommends that three additional part-time University lectureships in zoology be established from October 1; that an additional University demonstrators in zoology be established from October 1, and that a readership in invertebrate zoology be established for one tenure only, and that the General Board be authorized to appoint Dr. C. F. A. Pantin to this post from October 1.

Dr. R. N. Chopra, of Downing College, has been approved for the degree of Sc.D.

At Christ's College, Dr. R. D. Davies, of Gonville and Caius College, has been elected into a research fellowship. Dr. Davies was elected to a Salomons engineering scholarship in 1921, and was placed in Class I of the Mechanical Sciences Tripos in 1922. He is a University demonstrator in engineering and was formerly a captain in the Royal Engineers.

Sir David Chadwick, formerly a scholar of Sidney Sussex College, secretary of the Imperial Economic Committee and of the executive council of the Imperial Agricultural Bureau, has been elected an honorary fellow of Christ's College.

LONDON.—University postgraduate studentships of the value of £150 for one year have been awarded to W. J. Allum (Imperial College—Royal College of Science), W. J. Arrol (Queen Mary College and Imperial College—Royal College of Science), Elizabeth Carey (University College), J. A. Kitchener (University College), D. McMillan (University College), J. D. Marcantoni (Queen Mary College), Dorothee Metlitzky (University College), A. A. Ruddock (University College, Southampton) and Elizabeth Sweeting (Royal Holloway College).

The University studentship in physiology of the value of £100 has been awarded to J. P. Quilliam (University College) who will carry on physiological research at University College.

O. A. Saunders has been appointed as from October 1 to the Clothworkers' readership in applied thermodynamics tenable at the Imperial College—City and Guilds College. Since 1932 he has been lecturer in applied mathematical physics at the College.

OXFORD.—Sir Farquhar Buzzard, Christ Church, and I. O. Griffith, Brasenose College, have been elected to the Hebdomadal Council.

Dr. A. D. Gardner, University College, has been appointed to the new readership in bacteriology as from October 1. The title of professor has been conferred on Dr. A. D. Gardner. Dr. A. H. T. Robb-Smith has been appointed assistant director of pathology at the Nuffield Institute.

The senior mathematical scholarship for 1937 has been awarded to G. L. Camm of Balliol and New Colleges.

Dr. H. M. Sinclair, Oriol College, has been elected to an official fellowship and tutorship in physiology at Magdalen College. Miss M. G. Adam, senior scholar of Lady Margaret Hall, has been appointed assistant tutor in science at St. Hugh's College. At Christ Church, J. F. Hope Simpson (Balliol College) has been elected to a senior scholarship for work in botany and J. A. Moy-Thomas re-elected to a lectureship (the equivalent of a research fellowship) in zoology.

J. A. Boycott, Brasenose College and Miss E. J. Cookram, Society of Oxford Home-Students, have been granted degrees of M.D. Dr. N. O. Wright (Christ Church), of the Rowett Institute, has been granted the degree of D.Sc. for his work on proteins.

At Queen's College, M. Abercrombie has been elected to a junior research fellowship for work in zoology and E. P. Abraham, New College, to a readership for work in chemistry.

R. Campbell Thompson, Merton College, has been elected Shillito reader in Assyriology in succession to the late Prof. S. Langdon.

ST. ANDREWS.—At a graduation ceremonial to be held on September 28 in connexion with the celebration of the quarter-centenary of St. Mary's College, the honorary degree of LL.D. is to be conferred on Sir Leonard Woolley, archaeologist, among others.

The following appointments have recently been made: J. Dewar to be lecturer in chemistry in the United College, St. Andrews; T. G. Cowling to be lecturer in mathematics, and R. E. Stedman to be lecturer in philosophy, both in University College, Dundee.

Science News a Century Ago

The Grand Junction Railway

THE most important addition to the railways of Great Britain in 1837 was the Grand Junction Railway, uniting Birmingham with Liverpool and Manchester. The Bill for the line had been passed in 1833, and in 1834 the directors appointed George Stephenson and Joseph Locke as joint engineers. Stephenson withdrawing in August 1835, Locke became engineer-in-chief, and the line was constructed under his supervision. The opening of the line took place on July 4, 1837, when a train left Newton on the Liverpool and Manchester Railway at 7.0 a.m. and, after stopping at Crewe, Stafford and other places, finally arrived at Birmingham at 11.30 a.m. The distance was 82½ miles. Describing the events of the day, the *Morning Herald* said: "From Wolverhampton to Birmingham a general holiday appeared to be observed and the scene was highly interesting both to the observed and observers. Tents were pitched in several fields, and parties given by the respective tenants in honour of the day. The weather was extremely beautiful, and the freedom from dust which exists on railways is another interesting feature connected with this branch of mechanics." Among the most notable works on the line was the Dutton Viaduct, over the valley of the River Weaver.

Death in the Candle

UNDER this sensational heading the *Lancet* of July 8, 1837, contains the following account of a meeting of the Medico-Botanical Society held on June 28: "Mr. Everett detailed the results of several experiments made with the view of ascertaining the constituents of some 'new composition candles' which have lately been much employed by the public. His attention had been called to the subject by his having detected a strong garlic odour from the burning candles similar to that given out during the combustion of metallic arsenic. He purchased candles from various vendors of them, and, after considerable trouble, discovered a method by which he could collect a large quantity of the condensed smoke given out during their burning. He broke off the bottom of a glass retort with a very long neck, and placed the burning candle under it, the smoke having to traverse the lengthened tube was deposited on its sides. On carefully collecting this matter, and subjecting it to all the most unequivocal tests for arsenic, that metal was in every instance detected. The quantity contained in each candle would, according to the quantity collected by the experimenter, be about two grains; but in consequence of the difficulty in preventing the escape of a large quantity of the smoke, he considered that double that quantity might be fairly inferred to be present. He supposed the makers of the candles used this metal for the purpose of giving the candles a better appearance, and to give them a higher melting point, and this had since been acknowledged to him by a manufacturer of them, as the fact, the arsenic being found an excellent substitute for a small quantity of wax which answered the same purpose. Now, the question was to be decided whether or not this quantity of arsenic burnt in a room was injurious. . . . He (Mr. E.) would say that the vapours of metallic arsenic were fully as if not more noxious than those of sulphuretted hydrogen."

Medical Practitioners in Russia

THE *London Medical Gazette* of July 8, 1837, contains the following account of medical practitioners in Russia at that time:

"There are several classes of practitioners, but the deference paid to each is not in a ratio with their medical, so much as their military or civil rank. The degrees conferred by the universities are the following: Physician, Surgeon-in-Chief; Surgeon-in-Ordinary; Staff Surgeon; and Surgeon's Mate; Hospital Mate; Barber Surgeon; Apothecary. In general practice there is no positive distinction in the labours allotted to the first three ranks. The physician and the surgeon, in most cases, practise indiscriminately all branches of the profession. The physician receives homage from the surgeons, takes precedence as he passes through the wards of the hospital, signs documents and makes valid his rank by several operations. The hospital mates dressed in military uniform, march up and down the wards, half face about and stand to attention, as their superiors command them. The hospital mates and surgeon's mates are completely under military control, although attached to civil institutions. The apothecaries . . . are mere vendors of drugs and preparers of recipes, and their shops are all licensed by Government. . . . The last class is the *Tsivulnik* or barber surgeon, and is a numerous and thriving brotherhood. It falls to their lot to bleed, cup, draw teeth, apply leeches, and perform other little odd jobs of minor consequence. . . . There are no distinct aurists; aural surgery forming part of the practice of ordinary surgeons. There are likewise but few oculists who devote their whole time to diseases of the eye. Many physicians and surgeons include the treatment of these diseases in their general practice. Dentists abound in every street, and their profession is perfectly distinct, and not within the pale of the medical faculty. There are no distinct chiropodists in Russia."

Schönbein and Faraday

ON July 9, 1837, Schönbein wrote to Faraday, sending him copies of a book containing an account of his researches on iron dedicated by Schönbein to Faraday. He expressed his regret at not being able to visit England for the meeting of the British Association, and asked that a copy of his book might be presented to the Association if such gifts were received.

In the course of his letter, Schönbein said: "The other day I got a letter from Mr. Berzelius, the contents of which relate to my observations on the peculiar state of Iron. The distinguished Chemist, though he does not yet give a decided opinion upon the subject, is inclined to think, that in one notice of yours, published some time ago in the *Phil. Mag.*, which alludes to the observations of Ritter and de la Rive regarding the secondary poles and the electrical state of polar Platina-wires, the true cause of the inactivity of Iron is hinted at. According to the view of Berzelius, Iron performing the function of the positive Electrode undergoes a change with regard to its primitive electrical condition in such a manner as to be turned from a positive electrical body into a negative one. As my views with respect to electro-chemical subjects essentially differ from those of Berzelius, I cannot on this account think the ideas of that Philosopher correct. . . ."

Societies and Academies

Dublin

Royal Irish Academy, January 25.

E. J. CONWAY, J. M. O'CONNOR and D. K. O'DONOVAN: Influence of temperature on the activity of the kidney in relation to its influence on oxygen consumption. Expressing the secretory activity as an energy equation—with free passage of urea across the tubular cells—the slope of the oxygen consumption of the animal and that of the activity of the kidney with temperature are identical. On the curve of activity with temperature there appear three main phases similar to those on the oxygen curve, the latter being already described (O'Connor, *Proc. R.I.A.*). The diurnal variations of body temperature in the normal human subject (98.4° – 98.6° F. in the subject investigated) also show a temperature effect similar to that on total oxygen consumption, with minimum at 97.2° F., and the two main phases already described for renal activity (Conway) receive a satisfactory metabolic explanation. The lowest energy requirement for the maximum urea secretion was computed on the most general basis of an active secretion process, and found to be of the same order as that derived from the experimental values of the oxygen consumption as given in the general literature.

February 22.

E. J. CONWAY: Structural laws of the mammalian kidney with theoretical derivations. Details of certain structural laws of the mammalian kidney with theoretical derivation were presented. These were already briefly announced in *NATURE* of February 6, and referred to the agreement of the actual relationships with the following theoretical equations:

$$\begin{aligned} n \text{ (number of tubules)} &= W^{0.444} \times \text{a constant.} \\ l \text{ (length of the first convoluted} \\ &\text{tubule)} &= W^{0.111} \times \text{"} \\ g \text{ (diameter of the glomerulus)} &= W^{0.111} \times \text{"} \\ d \text{ (diameter of the first con-} \\ &\text{voluted tubule)} &= W^{0.444} \times \text{"} \end{aligned}$$

Paris

Academy of Sciences, May 10 (*C.R.*, 204, 1377–1448).

ALEXANDRE GUILLERMOND and ROGER GAUTHIER: The conditions under which neutral red produces the vital coloration of the vacuoles. For most of the fungi studied, the vital coloration of the vacuoles with neutral red is only possible in cells which have their growth arrested: as soon as the cells start growing they are decolorized. *Saprolegnia* and roots of wheat behave differently, and always accumulate neutral red at the commencement of their growth.

JEAN BOSLER and HENRI ROURE: The disappearance of Biéla's comet. In 1867, C. Bruhns pointed out that Biéla's comet in January 1848 passed near the orbit of the Leonids; if the orbits met, this might account for the disappearance of the comet. The author's calculations confirm those of Bruhns.

NICOLAS KEYLOFF and NICOLAS BOGOLIOUBOFF: Probabilities on chains.

Z. WARASZKIEWICZ: Topologically homogeneous plane curves.

CHI-TAI CHUANG: A generalization of a theorem of Valiron.

ROBERT FORET: The iteration of certain linear substitutions.

HENRI MILLOUX: The meromorphic functions in a circle.

ARNAUD DENJOY: The approximation of certain sums.

DE MIRA FERNANDES: The calculation of the energy of acceleration of a solid body.

LUCIEN MALAVARD and JOSEPH PARRIS: The boundary wall corrections in elliptical wind chambers.

GUSTAV ANDRÉ MOKREYOKI: The work required from starting an aeroplane to the point at which it leaves the ground.

JEAN LOUIS DESTOUCHES: The interaction of two corpuscles in relativistic wave mechanics.

JEAN ROUBAUD-VALETTE: The interpretation of the operators employed by Dirac by means of the fundamental magnitudes of hyperspace.

PHILIPPE TONGAS: A new empirical expression for the total heat of superheated steam.

THEODORE V. IONESCU: A new oscillator with very short waves (microwaves). The apparatus described and illustrated gives an oscillation of wavelength 36 cm.

MME. ARLETTE TOURNAIN-VASSY: The relative measurement of the absorption coefficients of ozone in the region of the Chappuis bands.

LÉON CAPDECOMME and PIERRE JACQUET: The reflecting power of copper. Polishing by the anodic method gives copper surfaces the reflective power of which is more constant and less alterable than surfaces obtained by the usual mechanical method.

MME. WILLY A. LUB: The optical spectrum of actinium. Actinium is the only element the optical spectrum of which is unknown. Starting with lanthanum oxide containing actinium, the wavelengths of seven new lines have been measured which appear to be due to actinium.

F. BARILLET and MME. A. CHOENARD: The evolution of the interfacial tensions in the neighbourhood of saturation.

FRANÇOIS BOURION, E. ROUYER and MME. O. HUN: The determination of the individual hydration of the ions.

MME. HENRIETTE SCHUHLER: The ultra-violet spectral properties of salicylic acid as a function of the pH.

VICTOR AUGER and MME. NINA IVANOFF: The molybdenum blues. A phosphoceruleomolybdic acid.

HALDUN N. TERREM: The corrosion of beryllium bronzes.

GEORGES LAUDE: The formation of ammonia by boiling some proteins with solutions of potash.

ROGER DE LARAMBERGUE: The synthesis of cyanamide by the oxidation, in the presence of ammonia, of some sugars, levulose, arabinose, mannitol and glycerol.

FRANÇOIS KRAUT: The breccias and conglomerates of the neighbourhood of Rochechouart (Haute-Vienne).

ANTONIO DE MEDeiros GOUVEA and GEORGES ZBYRZEWSKI: Observations on the Portuguese coast between the mouth of the River Odeceixe and that of Rio Mira.

ROBERT LAFFETTE: Some levels containing Foraminifera of the Cretaceous at Aurès (Algeria).

JOSUA HEILMANN HOFFET: The Cretaceous of Bas-Laos.

LÉVI HERMAN and MME. RENÉE HERMAN-MONTAGNE: The meaning of measurements relating to the quantity of dust or smoke shown at the ground-level.

JUAN CHAZZ: The production of choline in the caryopses and seedlings of dandelion, in relation with parasitism.

HENRI MARCELLET: The presence of a new C_{19} alcohol in the wax extracted from the oil of the fruit of the raspberry.

GEORGE BROOKS: The phosphorescent mineral matter in the bony tissues of the frog (*Rana esculenta*).

Amsterdam

Royal Academy (Proc., 40, No. 5, May 1937).

J. F. SCHOUTEN: The role of electric, photochemical and diffusion phenomena in vision. Quantitative determinations of the change in the sensitivity of the fovea produced by stimulation of a part of the retina by light.

F. A. VENING MEUNESZ: The gravity expedition of the Dutch submarine *O16* in the North Atlantic, January 11–March 16, 1937.

W. H. KESOM, MISS H. VAN DER HORST and K. W. TACONIS: Measurements concerning the volumes of mercury menisci. Determinations carried out by an X-ray method.

W. H. KESOM and P. H. VAN LAAR: (1) Measurements of the latent heat of tin in passing from the superconductive to the non-superconductive state at constant temperature. (2) Relaxation phenomena in superconductivity.

A. A. NIJLAND: Mean light curves of long-period variables. (28) Z. Ceti. (29) U. Persei. (30) S. Lynceis.

H. R. KRUYT and J. OOSTERMAN: Flow potentials on platinum.

J. TER BERG and F. M. JAEGER: The possibility of distinguishing right- and left-handed structures in crystals by means of their Laue patterns.

P. E. VERKADEN, J. VAN DER LEE and A. J. S. VAN ALPHEN: Researches on fat metabolism (10). Feeding experiments on dogs with simple saturated triglycerides.

H. A. BROUWER: Metamorphic rocks at Torne Träsk (Lappland).

K. MAHLER: Arithmetic properties of a class of decimal fractions.

V. LEVIN: Two remarks on van der Corput's generalization of Knopp's inequality.

W. H. ARIZ and J. OUDMAN: (1) Influence of aggregation on the transport of asparagine and caffeine in the tentacles of *Drosera capensis*. (2) Transport of introduced nitrogenous substances in the leaves of *Vallisneria spiralis*.

L. A. H. BOUWMAN: A new species of the genus *Sabinia*.

G. P. FRETZ: The relation of head length and head index of Johanneen and the spurious correlation of Pearson.

Moscow

Academy of Sciences (O.R., 14, No. 5; 1937).

S. FINIKOV: Laplacean suites with two projectively applicable congruences.

A. ANDRONOV and L. PONTEJAGIN: Gross systems.

E. LEONTOVIČ and A. MAYER: Trajectories which determine the qualitative structure and the division of the sphere into trajectories.

L. KANTOROVICH: The sequence of linear operations.

H. HILMY: A property of the minimal ensembles.

S. N. VERNOV: Measurement of cosmic rays in the stratosphere at the magnetic latitude 35° .

A. S. KOMPANILETZ: Absorption of sound by crystals at high temperatures.

S. A. UKHOLIN: Influence of temperature on the combined spectrum of carbon tetrachloride in the liquid and gaseous states.

P. BAZULIN: Influence of temperature on the absorption of ultra-sonic waves by benzene and carbon tetrachloride.

P. P. LAZAROFF: Thermic theory of changes in the peripheral visual sensibility due to geophysical causes.

P. P. LAZAROFF and I. A. LOURIN: Adaptation in peripheral vision in normal and imbecile infants.

K. A. KRAKAU, E. J. MUKHIN and M. S. HEDERICH: Equilibrium diagram of the ternary system Na_2SiO_3 — $PbSiO_3$ — SiO_2 .

S. FRISCH: The $^3P_2$ — ^3P term combination in the arc spectrum of cerium.

V. V. CHLIMOV: Compounds of quinones with HCl , H_3PO_4 , CH_3COOH , and their chlorination.

N. K. PÄENOV: A new type of iridium compound.

A. V. SOLOVJEV: Electrochemical investigation of the anti-corrosive properties of sodium nitrite.

A. F. SOSENKO: Geochemical diagram of pegmatites of the principal arcs of mountain chains of Central Asia.

J. LARIONOV and J. M. TOLMAČEV: Chemical composition of cassiterites.

M. GUDLET and E. KARDO-SYSOJEVA: Oxidation of ascorbic acid (vitamin C) in plants.

V. S. SADIKOV: A new method of isolating amino acids, peptides and cyclopeptides from protein hydrolysates.

J. D. POLJAKOV: A new apparatus for measuring the oxygen consumed by small aquatic animals.

Vienna

Academy of Sciences, March 11.

LUDWIG ECKHART: Affine representation and axonometry. A method is given for the construction of the projection of a body in any plane from its ground plan and elevation.

KARL FIEDERHOFER: Calculation of the normal modes of vibration of a spherical shell.

ALFONSO KLEMMENC and WALTER NEUMANN: Exact estimation of a nitric oxide—nitrogen dioxide mixture by the methods of gas analysis.

ERNST STORFER: Precipitation of trithiocarea cuprous chloride from its aqueous solution.

F. BILGER, W. HALDEN, E. MAYER-PITTSCH and M. PRISTEMER: Fatty matter in yeast (5). Quantitative relations in the biological formation of ergosterin.

W. JORDE: Thermal polymerization of styrol.

WALTER HÄUSELMAYER: Chemical development of the markings of butterflies. Wings extracted from the pupae develop markings when placed in tyrosinase. This action of tyrosinase is hindered by uric acid.

MARTEA GEIRINGER: Influence of the central nervous system on the adaptation of the colour of the frog (*Hyla arborea* L.). Severing the nerve connecting the regio chiasmatica to the pituitary destroys the ability of the frog to adapt its colour to its surroundings, while leaving the eyesight unimpaired.

GUSTAV GÖTZINGER: Geological analysis of the Quaternary deposits in the Traun valley region above Gmunden. The hydrographical state of the valley during various periods of recession of the main glacier is determined.

Forthcoming Events

SOCIETY OF CHEMICAL INDUSTRY, July 5-9.—Annual Meeting to be held at Harrogate.

MUSEUMS ASSOCIATION, July 5-9.—Annual Conference to be held at Newcastle-upon-Tyne.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

ASSISTANT CIVIL ENGINEERS (male) in the Air Ministry—The Secretary (S.2(c)), Air Ministry, Adastral House, Kingsway, London, W.O.2 (July 5).

TWO CHEMISTS and TWO JUNIOR ASSISTANT METALLURGISTS in the Royal Ordnance Factories at Nottingham and Birtley—The Chief Superintendent of Ordnance Factories (Advert. No. 144), Royal Arsenal, Woolwich, S.E. 18 (July 6).

LECTURER IN MINING SUBJECTS and a LECTURER IN MECHANICAL ENGINEERING in the Mining and Technical College, Onnch Street, Barnsley—The Principal (July 6).

A TEACHER OF MATHEMATICS AND PHYSICS with a knowledge of rubber technology, in the Northern Polytechnic, Holloway, London, N.7—The Clerk to the Governors (July 7).

LECTURER IN CIVIL ENGINEERING at Wigan and District Mining and Technical College—The Principal (July 7).

ASSISTANT ENGINEER INSPECTOR (MECHANICAL) for service in Great Britain in the Office of the High Commissioner for India—The Director-General, India Store Department, Belvedere Road, S.E. 1 (July 7).

A GRADUATE IN MECHANICAL ENGINEERING to teach mathematics and engineering subjects in the North-east Essex Technical College, Colchester—The Clerk to the Governors (July 7).

ASSISTANT LECTURER IN MATHEMATICS in the Huddersfield Technical College—The Director of Education, Education Offices, Peel Street, Huddersfield (July 7).

TEMPORARY ASSISTANT LECTURER IN BOTANY in the University of Liverpool—The Registrar (July 7).

DESIGNER (Ref. No. 542 B) and ASSISTANTS II (Ref. No. 296 B) in the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (July 9).

SCIENTIFIC OFFICER, ASSISTANTS III (male and female) in the Ballistics Directorate, Research Department, Woolwich, S.E. 18—The Chief Superintendent (July 9).

PRINCIPAL of the County Technical College, Guildford—The Chief Education Officer, County Hall, Kingston-upon-Thames (July 10).

LECTURER IN CHEMISTRY at Brighton Technical College—The Education Officer, Education Offices, 54 Old Steine, Brighton 1 (July 10).

ASSISTANT CIVIL ENGINEERS (male) in the Civil Engineer-in-Chief's Department, Admiralty and H. M. naval establishments at home and abroad—The Civil Engineer-in-Chief, Admiralty, London, S.W. 1, envelope marked "A.C.E." (July 12).

CITY ENGINEER of Kingston-upon-Hull—The Town Clerk, Guildhall, Hull, envelope marked "City Engineer" (July 12).

TECHNICAL OFFICER in the METEOROLOGICAL OFFICE—The Secretary (S.2 A), Air Ministry, Adastral House, Kingsway, London, W.O.2 (July 12).

LECTURER IN MATHEMATICS in the Manchester Municipal College of Technology—The Registrar (July 12).

DEPUTY OF THE Technological Research Laboratory at Calcutta of the Indian Central Jute Committee—The High Commissioner for India, General Department, India House, Aldwych, London, W.O.2 (July 12).

LECTURER IN MATHEMATICS at the Cheltenham Technical College, Lansdown Road—The Secretary (July 12).

SENIOR SCIENTIFIC OFFICER (male) in the Admiralty Scientific Pole—The Secretary of the Admiralty (C.B. Branch) (quote O.H. 4561/37) (July 17).

CHEMIST in the Geological Survey Department, Federated Malay States—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, London, S.W. 1 (July 31).

PART-TIME LECTURER IN BIOLOGY (woman) in Sedgley Park Training College, Manchester—The Principal.

MECHANICAL and ELECTRICAL ENGINEER in the Public Works Department, Gold Coast—Crown Agents for the Colonies, quoting M/5220.

ENGINEERS for the Public Works Department, Somaliland—Crown Agents for the Colonies, quoting M/5076.

CIVILIAN LABORATORY INSTRUCTORS at the Electrical and Wireless School, Royal Air Force, Cranwell—The Principal.

TEMPORARY ASSISTANT ENGINEERS, ENGINEERING ASSISTANTS and JUNIOR ENGINEERING ASSISTANTS in the Ministry of Transport for work in connection with surveys of trunk roads—The Establishment Officer, Ministry of Transport, Northumberland Avenue, London, W.O.2.

EXAMINERS in the Aeronautical Inspection Directorate Test Houses—The Secretary (S.2(d)), Air Ministry, Adastral House, Kingsway, W.O.2.

Citizenship

AT the recent conference of the Association of Teachers in Technical Institutions, Mr. W. E. Park referred in his presidential address to a report on training for citizenship for students in technical institutions which had been prepared by his Association in conjunction with the Association of Principals of Technical Institutions and the Association of Technical Institutions. The report has just been issued, and is one which we believe ought to be regarded as of first-class importance.

The reasons for our belief are not far to seek. A glance about the world reveals its present discontents with an uncomfortable vividness. The old values which seemed once so secure are fading. Human organizations, which seemed but a few years ago to be leading, however slowly, to sane and rational ends, are crumbling. Over-production on one hand and even starvation on the other become more sharply defined. Political ideas appear charged with a newer and more emotional violence. The dream of a world-State shatters down to a grim reality of nations self-contained, self-striving and living in a fear-haunted hostility which keeps us on the brink of unimaginable dangers. If we are not, at the moment, living under the actual threat of war, we are daily made aware of rearmament and the need to be prepared for what can be little else than the crash of civilization as we know it. Yet, in spite of the distinguished writer who informed us with grim courtliness that we are witnessing a race between education and catastrophe, it would seem, in Great Britain, at any rate, that the world of education moves on with calm serenity and is by no means convinced that, if it neglects the problems which none of its students can ultimately

avoid, it neglects a vital duty. Whatever we may think of dictator countries, they have at least learned to use the machinery of their schools. They have infused education with their own enthusiasms and made it aware of its part in the life and work of the community.

Sir Ernest Simon, chairman of the Association for Education in Citizenship, has summed up the aims of that education under four heads : a sense of social responsibility ; a love of truth and freedom ; the power of clear thinking in everyday affairs ; a knowledge of the broad political and economic facts of the modern world. Those aims are ambitious, and we would hesitate even to attempt to sketch the means whereby they might be attained. We know perfectly well that those responsible for any kind of school can point to their time-tables and syllabuses and ask where and how they are capable of addition. They can say, broadly, that the aims are inherent in their present work. But the problem has an urgency which will not permit it to be so easily dismissed. The manipulation of time-tables and syllabuses is a matter for experts, and none would be so bold as to say that it may not be somehow used to make education that very real thing—*adaptation to environment*. Inherent qualities, too, need more discussion than the phrase sometimes permits. We have long since given up the belief that training in one subject necessarily gives facility to deal with another. If that were so, we should find that our specialists were invariably wise and their judgment, outside their specialist field, invariably sound. But we know that is not the case. The specialist in physics cannot necessarily be regarded as being free from prejudice, emotion and even ignorance when he is asked to make a judgment

on the League of Nations or the need for tariff reform. Clear thinking, in short, cannot be transferred from specialist subjects to others with which the voter has to deal in everyday life.

Whatever may be done in other fields of education, then, it is clear that those concerned in technical education are to be encouraged in their attempt to view the problem of education for citizenship from the point of view of their own work; for it is a task which presents the utmost difficulties when any *direct* method of teaching the subjects which citizenship may include is attempted. Naturally, if and when other branches of education take up those subjects, it is a task which will become correspondingly easier.

A large body of the students of technical institutions are those who take part-time courses. They are engineers, chemists, builders and the like, who are already in employment. Since they attend courses on some three evenings per week, and since they have to undertake homework in addition, and since their work is directed to the attainment of some recognized professional or industrial qualification, it is difficult to see how it can be possible to secure their attendance for additional, and, at first sight, 'unrelated' subjects. For these students there is the possibility of the 'indirect' method. If education for citizenship means training the individual for his relationship to the various communities on which he impinges, it is certainly within the bounds of possibility—to put it no higher—that specialist subjects could be used by skilful teachers so that their backgrounds, contacts and relationships could be shown in the everyday world. The discussions and debates of students' societies, too, could be used. One imagines, for example, engineering and commercial students dealing with problems of production and distribution—under happier titles, perhaps—and arriving at conclusions concerning duties and relationships which normally they might miss.

For full-time students we hope more can be done. In their case it ought to be possible to apply the 'direct' method. The introduction of studies of the social sciences, the structure of government, modern political and industrial problems would, in our opinion, be of immense value in attaining the ends we have in mind. It is not for us here to suggest the precise subjects, their method of treatment or their particular place in particular curricula. It may be that the use of daily papers—with a view to comparison of opposing views on a single issue which are so

constant a feature of our modern daily Press—will take the place of the more orthodox text-book. (Such a method would, at least, train students to sift evidence and arguments for themselves rather than be swayed by the prejudice of partisan announcements.) It may be that local circumstances could be used to demonstrate problems of town-planning, means of transport, food supply, organization of community life, local and central government. Whatever the method, if an active interest in the social and political structure can be developed, the first step towards attainment of the aims of citizenship will have been secured.

It may be objected that this kind of teaching involves a danger of bringing politics into education. We would reply that, if a scientific approach to social and political problems be not taught, young people will be left unprotected, both now and in later life. Which is the greater danger?

We would make it very clear, even to the point of what may appear unnecessary reiteration, that we have no wish to make dogmatic suggestions as to subjects or to their treatment. It is desired only to emphasize that the social sciences must, in some way, be made to keep pace with the other sciences, which are setting expected, as well as unexpected, problems to our civilization. Articles in these columns from time to time have underlined the fact that, in spite of the advances of science and the obvious advantages which these have brought to us, we stand in the face of vast dangers all of which point urgently to the need of adapting our social life to the new and changing environment which men's activities have produced. The technologist and the scientific investigator should not be allowed to work in specialized compartments with no picture of how their work is related to the rest of the community. For want of a better name, we call the presentation of that picture 'citizenship', which Aristotle saw as "the most synthetic of sciences" and, as a practice, "the most architectonic of the Arts". His notion of civics was expressed under the four types of co-operation between the labour of the people, the public functions of citizens, the meditations of philosophers, and the efforts of teachers. It is a notion which we moderns, in our present dangers, should not neglect. For that reason, we welcome the publication of the report prepared by the three technical associations, and we look forward to its implementation in no matter how experimental a form.

Man and the Machine Age

Die Tragik des technischen Zeitalters
Mensch und Maschine im 19. Jahrhundert. Von
Otto Veit. Pp. 226. (Berlin: S. Fischer, 1935.)
n.p.

THE book under notice deals with a problem which has become very familiar to the German philosophers, sociologists and others since the days of Nietzsche. To put it very briefly, it comes down to this: the victory of rationalism, materialism, liberalism, individualism, and the achievements of the 'technical age' which originated from the victory in question, have become a fatal gift for the human race. It is true that the introduction of machinery into productive processes enabled the population to grow more rapidly and to be supplied with material goods more abundantly than ever before; but, at the same time, there opened a wide gulf between the 'objective' and the 'subjective' culture. Mankind has become richer in material wealth; man has become poorer.

Strange as it may seem, this judgment is justified in regard not only to man's emotional but also to his intellectual qualities; the philosopher who commanded all the knowledge of his time and was able to lift it up on a higher plane has been supplanted by the specialist who confines himself to a more or less narrow sphere of scientific comprehension. The political and economic freedom for which our forefathers fought so enthusiastically has changed into a universal dependency; the maintenance of liberal institutions in some major imperialistic countries does not alter this fact, but makes it still more impressive.

Finally, liberty of thought has become a rather negative character; we know the chains from which we are free (or from which we desire to be free), but we do not know exactly for what purpose we are free. Religious dogmas have lost that influence over the human mind they formerly exerted; the same fate has befallen the belief in reason, freedom, humanity and progress, which seemed to replace the religious creeds in the period of the bourgeois revolutions. This intellectual development inevitably results in a radical relativism which may discuss every thinkable opinion without taking sides with or against any one of them, and in scepticism and nihilism.

Two roads widely differing from each other seem to lead out of the cultural crisis; the first of them was indicated at the end of the eighteenth and beginning of the nineteenth centuries by thinkers like Burke in England, de Bonald, de Maistre, Chateaubriand in France, Adam Müller in Germany. These authors held the view that not the rational analysis but the somewhat irrational intuition ought to be regarded as the supreme method of scientific research; they placed emphasis on the fact that the genuine rights of the community are superior to those of the individual; they responded to the liberal admiration of progress and future with their worship of the past, the Middle Ages in particular. Consequently, they opposed the destruction of the traditional technique by modern machinery; they wanted the application of the latter to be kept down so far as possible, if not prohibited altogether.

The second attempt at a solution of the crisis has been made by socialism. The socialists did not lag behind the romanticists in acknowledging the damages inflicted upon culture by the bourgeois revolution. But the romantic criticism is reactionary and therefore, after all, it remains hopeless; the socialists, on the other hand, try to overcome the capitalist society in a progressive manner; they do not base their verdicts on the past but on the future. The socialists demand that those regions of social life which are centred upon technique and economics ought to be organized as rationally as possible; the predominant claim of socialism, namely, the replacement of private ownership in the means of production by common ownership, means in reality that the principle of rational organization which—under capitalism—is necessarily restricted to the individual factory or trust, is to be extended over the whole field of economic relations. Nevertheless, socialist rationalism is not an end in itself; the underlying motive is the settled conviction that technique and economics, if they are to be made to serve man instead of being served by him, form the appropriate foundation of a "realm of real freedom" as it has been called by Marx.

It is very characteristic of the book under notice that Veit accepts neither the romantic nor the socialist solution. As regards his attitude towards the 'romantics', he is in accord with the vast

majority of the philosophers in fascist countries, who are in agreement upon many points with the feudal and clerical enemies of the bourgeois revolution but, at the same time, do not become 'romantics' in the strict or proper sense of the word. It is obvious why. The romantic flight into the Middle Ages, the veneration of the feudal monarchy, the nobility, the church and the corporations, have never been anything else but a counter-move against the use of liberal capitalism; and even in this respect their practical significance was limited to the period when modern technique and large-scale production were at their very beginning. Such currents like national socialism (or fascism in general) have sometimes been regarded as a set-back into a precapitalist state of society from which the present civilization is to be protected. People who argue along these lines are inclined to confound the ideological veil with the social reality that the former has to cover. National socialism, in the very interests of rearmament and imperialistic expansion, is forced to develop the applied sciences; and the big profits which have been made in Germany, Italy and other fascist countries have not benefitted the peasants, the handicraftsmen or the small shopkeepers but the heavy industrialists, who invest them either in their own or in similar undertakings, thus enlarging the domain of machinery and rational technique.

The charges made by Veit against his second and more dangerous adversary, dialectical materialism, testify to the fact that Marx has been more frequently criticized than understood. Veit is of the opinion that—according to Marx—the worker has been enslaved by the machine. Even a very superficial knowledge of the Marxian system gives ample proof that the above-mentioned representation of the Marxian philosophy is utterly misleading. Marx never speaks of 'the machine' without further specification, that is, without regard to the social system in which 'the machine' is being conducted, but he draws a clear and sharp distinction between the results brought about by the machine in capitalism on one hand, and in socialism on the other; this differentiation may be right or wrong, but it is impossible to criticize a thinker for ideas he never propounded.

Since Veit neither shares the romantic nor the socialist point of view (each of which is consistent in itself), his own literary contribution towards the solution of the cultural crisis remains exceedingly vague and unprecise. He does not cross the border which had already been reached by Nietzsche and others; logically he lags far behind his predecessors. Against the will of the author, his book has become a justification of that critical stage of development in the overcoming of which he wishes to co-operate.

ALFRED MEUSEL.

Palæocene Mammals

Paleocene Faunas of the San Juan Basin, New Mexico

By W. D. Matthew. (Transactions of the American Philosophical Society, New Series, Vol. 30.) Pp. viii + 510 + 65 plates. (Philadelphia: American Philosophical Society; London: Oxford University Press, 1937.) 22s. 6d. net.

GREAT strides have been made in recent years in the field of mammalian palæontology, and the evolution of some at least of the orders of mammals are now set out with a great wealth of detail. Osborn's great monograph of the Titanotheres, for example, or his history of the Proboscidea, of which the first volume has recently appeared, show in a very striking manner not only how great is the amount of material on which to work, but also how complex has been the course

of evolution of the mammalian orders. These works, however, and others similar, do not, as a rule, begin their story before the Eocene, by which time the orders dealt with had become well established. Their 'pre-history' and inter-relationships, therefore, are not elucidated.

Simpson's classical monographs on the Mesozoic mammals have given us all the information that is as yet possible as to the dawn of mammals from their reptilian ancestors and of their evolution up to the, as yet little known, Cretaceous period; but thereafter until the Lower Eocene, by which time the mammalian orders had for the most part become defined, there has been a serious gap in our knowledge. At one time, this hiatus seems to have been considered as a comparatively small affair termed merely the 'Basal Eocene'. Now, as the Palæocene, it takes rank as one of the

major divisions of the Tertiary, equivalent in importance with the Eocene, Oligocene or other of the periods.

The late Dr. W. D. Matthew's monograph on the Palaeocene faunas of the San Juan Basin of New Mexico, as a résumé of previous information and a great addition of new, is a most important contribution to the early history of mammalian evolution. The San Juan formations yield a series of deposits ranging from the Upper Cretaceous, separated by an unconformity from the Puerco, Torrejon and Tiffany beds of the Lower, Middle and Upper Palaeocene respectively, to the Wasatch beds of the Lower Eocene. This covers a great range in time, and the faunal list of mammals (a smaller list of reptiles is also included) is impressive with its forty, or more, genera distributed among fourteen families and no less than seven orders. A few of these, such as the Multituberculates, are remnants of the earlier Mesozoic radiation that were dying out, but among the Creodonts, Condylarthra and Insectivora may be sought the foundation members of our modern mammals, and by implication some picture may be made out of the centralized common ancestors all of which must have flourished during the little-known Cretaceous period. A diagram is here reproduced (Fig. 1) which shows, in a summary form, the author's conclusions as to the relationship of the mammals of the period and, incidentally, where our knowledge is still lacking. The bulk of the volume, after a short explanatory introduction, is devoted to a systematic and descriptive revision of the Palaeocene mammals of New Mexico, and is followed by some general observations and conclusions. The descriptions of the various species, the eighty text figures and sixty-four quarto plates leave nothing to be desired.

No one familiar with Matthew's numerous other contributions would expect the general observations and the discussion which conclude the work to be other than stimulating. The origin and evolution of the multitubercular tooth, the characters of the feet and limbs from their primary types and of the skull and

skeleton generally, all receive illuminating treatment, as also does the account of the correlation of the different faunas and the origin and evolution of the tertiary mammals as a whole. The last word on this great assembly of early mammals has yet to be said. Many species are still known only from fragments, and the patient collecting which began under Cope so far back as 1880 must still go on in order to fill up the gaps in our knowledge. All future workers in this field will turn to the present volume

Fig. 1.

RELATIONSHIP OF THE MAMMALS OF THE CRETACEOUS. FROM MATTHEW'S "PALAEOCENE FAUNAS OF THE SAN JUAN BASIN, NEW MEXICO".

as a classic for guidance and inspiration.

Although the editors (Prof. W. K. Gregory, Dr. Granger and Dr. Colbert with the assistance of Dr. Simpson) state that their work has been limited to an "addition of references", the thanks of all workers in mammalian palaeontology are due to them for the labour of seeing the volume through the press so efficiently, and to the Trustees of the American Museum and to the American Philosophical Society of Philadelphia for their public spirit in making possible the publication of so useful and important a work.

C. F. C.

Adsorption Columns

Die Chromatographische Adsorptionsmethode: Grundlagen, Methodik, Anwendungen. Von Prof. Dr. L. Zechmeister und Dr. L. v. Cholnoky. Pp. xi+231. (Wien: Julius Springer, 1937.) 14.40 gold marks.

WHEN Tswett, to whom the authors of this book refer as "genialer russischer Botaniker", first used the chromatographic absorption method for the separation of chlorophyll *a* from chlorophyll *b*, he was probably quite conscious of having introduced at least a novel application of physical phenomena that themselves may have been already known to many. He can, however, have had no conception of the extraordinary variety of compounds to the separation of which the method was to be applied in the following thirty years; indeed the very existence of these compounds was in many instances unknown in Tswett's time.

The adsorption of a solute upon a solid insoluble in the solvent of the solution had been recorded many times, and even used as a means of separation, when Tswett conceived the idea of making the solution flow in one direction—vertically downwards—through a column of the adsorbent, so that the adsorbed material might afterwards be desorbed; or 'eluted', by the same or some other more suitable solvent.

The solutes then arrange themselves in a series of bands, the distance of which from the top of the column is primarily determined by the 'adsorption potential' of the solute, the less easily adsorbed being found in the lower band. By the subsequent use of other suitable solvents, the bands may be 'developed', that is, the distance between them is increased, so that the column can then be cut, and the bands separated mechanically from each other. Alternatively, the principle of the 'liquid chromatogram' may be employed; in this application, the undeveloped bands are washed out *seriatim* into different containers, by using an eluent with solvent properties suitably related to the adsorption potentials of the materials in the various bands.

It is of more than historical interest to note that one of Tswett's original columns consisted of sucrose, his solvent being a suitable organic liquid. We have come to-day to think of adsorbents so much in terms of acid clays, alumina, calcium carbonate or hydroxide, and so on, that we are apt to forget the relativity of adsorbent, solvent and adsorbate.

The first, or general part of this book is divided into two chapters, on fundamental principles and

methods respectively. The special, or second, part is divided into three chapters, covering in turn natural colouring matters (including chlorophyll, prophyryns, carotenoids, naphthaquinone and anthraquinone dyes, flavones, pterines, anthocyanins, etc.), synthetic or artificial colouring matters, and various colourless or slightly coloured substances—among which occur terpenes, glycosides and aglycones, alkaloids, vitamins, enzymes, and so on.

The information given about the application of chromatographic methods to such diverse substances is remarkably complete for a volume with only 190 pages of text (the rest of the book consists of a table of contents, some plates of photographic records, a bibliography with nearly 400 references, and both author and subject indexes). Moreover, the value of the book is further enhanced by some unusual tables, "thrown in", as it were, with a pound of chromatography. The complete list of carotenoids of known constitution, with their formulæ, in order of their adsorption-potentials, and, later, the list of all known carotenoids and derivatives, with their sources, show where the authors' personal special interests have lain, but there are no other signs of predilection in the book.

Since chromatography is essentially a method of *analysis*, it is rather surprising that analytical chemists have so far made very little use of it. In this book, the authors have only been able to cite a few isolated applications, as for example to the detection of falsification in the colour of wines, and even here the method is qualitative only, or at best semi-quantitative. When, however, the analyst has to separate two solid substances the chemical constitutions of which are sufficiently close to make separation by precipitation or crystallization either incomplete or impossible, precision chromatography would seem to offer a possible technique, provided the substances are reasonably stable in solutions of appropriate strength.

This admirable and comprehensive monograph by Prof. Zechmeister and Dr. v. Cholnoky, of the University of Pees, both well-known exponents of chromatography, to the literature of which they have themselves made valuable contributions, is about as good as such a book can be. Clearly produced, logically arranged, painstaking in its presentation of detail, exhaustive in its citation of examples—it is the complete handbook for the practising or would-be chromatographer. An English edition is urgently needed.

A. L. BACHARACH.

Reports of the Progress of Applied Chemistry
Vol. 21, 1936. Pp. 876. (London: Society of Chemical Industry, 1937.)

THIS volume appears so punctually year by year soon after the end of the period surveyed, and is so consistently full of well-digested reports, that every English-reading chemist must now be fully aware of its value; indeed, with many its appearance is reckoned an event. One reason for the welcome which always attends its arrival is evident; for after twelve months' struggle to keep one's head above the flood of chemical literature in which one is even mildly interested, a raft on which one may float awhile and contemplate the scenery is not to be despised. These surveys of progress in the several branches of technological chemistry appeal also to those who, having sufficient chemistry to follow their purport, are however not engaged in the work they describe, and perhaps would not regard themselves as chemists at all.

Among the new contributors are Mr. M. B. Donald (general, plant, and machinery), Dr. J. Grant (pulp and paper), and Dr. J. A. Sugden (refractories, ceramics, and cements), while Prof. W. E. S. Turner (glass) and Dr. D. F. Twiss (rubber) are old friends who have returned. This year the biennial report on explosives is included. There are 26 sections in all, with general name and subject indexes, and of course the information presented is lavishly documented, references being given both to original sources and to abstracts. It would probably be fair to describe the Report as a whole as "better than ever"; which means that it reflects steady progress both in technical achievement and in presentation. A. A. E.

Polychromatic Plates for Color Sense Examination
By Dr. E. B. Rabkin. Pp. 40+xx plates. (Kharkov: State Medical Publishing Board, 1936.) 30 roubles.

THIS series of tests for colour defect issues from the laboratory for colour vision of the Hirshman Memorial Ukrainian Central Ophthalmic Institute, of which Dr. Rabkin is the director. The tests are composed of coloured figures on coloured backgrounds, such as are found in the Stilling and the Ishihara tests. A number of the plates contain also 'hidden' figures, which are visible only to the dichromate. Triangles, circles and squares appear on some plates instead of figures, and so can be used for testing children and illiterates. A diagnosis can be made from the tables of dichromasy in general, and of protanopia, deuteranopia, and tritanopia in particular. The author claims, too, from the tests that "the simpler forms of anomalous trichromasy" can also be detected. Plates are added to detect simulation.

The series itself has been tested out in the Experimental Ophthalmic Clinic of the Institute of Experimental Medicine at Kharkov, and has proved successful. It seems, if one can judge from a preliminary survey, to give satisfactory results, and can be recommended. The book contains detailed and clear instructions in both Russian and English, although the English translation contains some curious phrases and sentences, and the spelling is not always of the best. MARY COLLINS.

Organic Syntheses:

an Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. L. F. Fieser, Editor-in-Chief. Vol. 17. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1937.) 8s. 6d. net.

PRODUCED on the plan now familiar to organic chemists and biochemists, the latest addition to this series contains details of thirty preparations. Among the open-chain substances are γ -aminobutyric acid, made by a modification of Gabriel's method; ϵ -aminocaproic acid, prepared from 2-ketohexamethylenimine; and 1,3-butadiene. It is stated that between 25 gm. and 30 gm. per hour of crude butadiene may be produced by passing the vapour of cyclohexene over a cracking element, in an ingenious apparatus which is here fully described with the aid of a diagram.

Of interest in carbohydrate chemistry is the account of the acetolysis of cotton, and of the hydrolysis of the resulting α -cellobiose octa-acetate according to Zemplén's method. Biochemists will also welcome the details given for the hydrogenation of cholesterol to dihydrocholesterol (β -cholestanol) and the oxidation of this to cholestanone. Under the heading of 2-carbethoxycyclopentanone (prepared from ethyl adipate) may be found a description of the useful Hershberg stirrer for pasty mixtures. Finally, the stereochemist is catered for in the precise directions given for the synthesis and complete optical resolution of that useful stereochemical agent, α -phenylethylamine. J. R.

Mechanistic Biology and Animal Behaviour

By Theodore H. Savory. Pp. xv+182. (London: Watts and Co., 1936.) 7s. 6d. net.

MR. SAVORY's book gives an eminently lucid and readable description of tropistic behaviour in some invertebrate organisms. The book, however, is largely devoted to an unconvincing exposition of certain well-worn theoretical issues. Mr. Savory defines his aim as the purely objective description of behaviour, which for the purposes of deterministic analysis he regards as the "visible response of an animal to some kind of stimulation which originates most frequently from a disturbance of its environment". He strays, however, from the logical demands of his definition, which is generally accepted by scientific students of behaviour, when he leaves the field of straightforward description. Thus, when he departs from the world of invertebrate organisms with which he is familiar, and discusses mammalian forms such as dogs, he accepts *a priori* concepts such as 'mind' and 'intelligent' as opposed to 'sub-intelligent' behaviour, and fails to realize that to the student of behaviour these concepts are somewhat empty. It is clearly illogical for the experimental investigator to ask whether spiders that lurk under stones have mind and self-awareness, and then to answer 'no' merely because the particular tropisms which drive spiders under stones have been defined.

The book closes with an uncritical statement about the influence of acquired habits on the course of arachnid evolution.

Measurement of Submarine Daylight

By Dr. H. H. Poole.

SUBMARINE measurements of solar radiation are of interest to oceanographers, who are concerned with such problems as the rate of rise of temperature of the water, the rate of photosynthesis, the movements of zooplankton, or the depth limits of daylight vision for fish. They also enable us to measure the opacity of the water, which, being an index of the amount of matter in suspension, may give valuable evidence as to its previous history, and is likely to be of importance in connexion with the nutrition and migration of fish.

A thermopile with suitable colour filters has been used by Birge and Juday to measure the total radiation, and that in different spectral bands, at various depths in American lakes, but for work at sea the measurement of the very small potential differences presents difficulties. As the spectral sensitivity range of the selenium rectifier photo-electric cell covers the band showing appreciable penetration through sea-water, it appears to be the most convenient instrument at present available for submarine work.

This cell has a range of sensitivity extending somewhat beyond both ends of the visible spectrum, with a maximum about $595\text{ m}\mu$ (that of the eye being about $555\text{ m}\mu$). It appears to be permanent, apart from temporary fatigue or temperature effects, which may amount to a few per cent in strong illumination. For small illuminations the current generated is proportional to the light, but in strong light the ratio current/illumination falls appreciably, and the necessary corrections must be found if the cell is to be used to measure intense illumination. The fall in this ratio with increasing illumination becomes much more important with a high-resistance external circuit, so that a low-resistance measuring instrument is always desirable, and sometimes essential.

The Weston selenium cell which has been used by Utterback, and also by Atkins and Poole, gives, when exposed under a sheet of opal-flashed diffusing glass, a current of one microampere for about 20 lux. With a 10 ohm galvanometer the sensitivity would fall to about 1 μ amp. per 25 lux in full sunlight. The Lange selenium cell used by Pettersson is more sensitive, giving 1 μ amp. for about 5 lux in weak light. The fall in sensitivity in strong light is, however, so great that the

cell must be protected by a suitable reducing screen when used to measure bright daylight. This screen must be removed for weak light readings.

The choice of a suitable instrument to measure the current presents certain difficulties, as the claims of current sensitivity, lowness of resistance, quickness of reading, and insensitivity to the motion of the ship, are not easily reconciled. Utterback has used a special marine galvanometer, Atkins and Poole a modified form of their potentiometer method previously used with emission cells, adapted so as to include the principle and advantages of the zero-resistance circuit devised by Campbell and Freeth, while Pettersson, aided by the greater sensitiveness of his Lange cells and the comparative steadiness of his ship, has found simpler pointer and light-spot galvanometers satisfactory in his work.

The cell mounted behind a strong glass window in a watertight case is lowered to any required depth by means of a wire and a spar projecting over the ship's stern, thus minimizing the shading effect of the ship and the vertical movements due to rolling. Utterback uses a case large enough to contain a set of colour filters, which can be interchanged by an electromagnetic device. This is a great advantage, but the size and complication of the apparatus are drawbacks, and most workers have contented themselves with the use of external filters laid on the window, which is generally horizontal, and changed by hauling the photometer on board. Above the colour filter is placed the opal diffusing glass, the use of which is rendered necessary by the varying obliquity of the illumination to be measured. The transmission of the colour filter is not affected by such variations in obliquity, as the filter is below the opal, and submarine light the obliquity of which is greater than 48° , and which would be prevented by internal reflection from reaching the cell if the diffusing glass were absent, can reach the internal diffusing layer in the opal glass and be duly measured.

The use of colour filters to limit the range of sensitivity is rendered necessary by the differential absorption of the water, which entirely alters the average composition of the radiation with depth, and thus alters also the sensitivity of the cell, so

that it is very difficult to interpret the submarine readings of a selenium cell without filter. The following Jena glass filters, each 2 mm. thick, seem to be suitable for general work: red, 720–600 m μ , RG 1; green, 600–480 m μ , VG 9; blue, 480–360 m μ , BG 12. The limits are only approximate and are affected by the falling sensitivity of the cell towards both ends of the spectrum.

The variations in the surface light must be observed by a second cell exposed under a similar filter and opal glass in a position on deck as free as possible from shading by spars and rigging. The photometer is directly compared side by side with the submarine photometer, and the simplest means of expressing the submarine illumination is as a percentage of the surface light in the same spectral band at the same instant.

It is more difficult to express the submarine illumination in definite units. The selenium cell, being more sensitive than the eye to both ends of the visible spectrum, does not differ very greatly from the latter in its estimate of common illuminations of different predominant colours. Thus, if it is standardized with a filament lamp at a colour temperature 2,360° K., it appears to under-rate average sunlight by some 10–20 per cent. The use of a higher temperature source for standardization reduces this discrepancy, and some workers have used for this purpose the Davis-Gibson colour filter, reproducing with fair accuracy average noon sunlight. We can then express in 'lux' the reading of a cell exposed without colour filter in air, without introducing any serious error, by the use of a term which is strictly only applicable to visual measurements. With colour filters, however, or under water, which acts as a colour filter, this quasi-visual scale becomes meaningless and misleading.

The ideal procedure is evidently to express the results in terms of the radiant power in the different spectral bands, say, in microwatts per square centimetre. Clarke has used this method of presentation for his work with emission cells in the western Atlantic, and Atkins and Poole have also standardized some of their cells in power units. The lowness of the colour temperature of all ordinary sources, however, limits the accuracy of the standardization, and has led Angström to suggest a method of standardization by means of sunlight which may prove to be the best available.

There is general agreement between the results obtained by workers on both sides of the Atlantic and in the north-eastern Pacific, the large variations in the opacity of the water found by all being obviously due to local conditions. The clearest water so far recorded was found by Clarke in the Sargasso Sea. Working down to 180 metres,

he found a value as low as 0.03 for the extinction coefficient of blue light. This means that the fall in the illumination on a horizontal surface was only 3 per cent per metre, the light falling to one tenth of its value at about 80 m. depth. In this water both green and violet light gave coefficients close to 0.05, while for the light passing through an RG 1 filter Clarke found a coefficient 0.08 for depth range 20–80 m. This is an extraordinarily low coefficient for 'red' light, and may possibly be due to the action of the overlying water layers (in which the absorption was much more rapid) in removing all wave-lengths much longer than 600 m μ , leaving only a very narrow spectral band of orange-red.

In coastal waters higher coefficients are always found, the absorption of the shorter waves increasing more rapidly than that of the longer. Thus, in both the English Channel and in the north Pacific the coefficient for blue and green is generally about the same, and not far from 0.1 at a distance of 20 miles off shore, the illumination falling to one tenth of its value every 23 m., the corresponding average figures for red being 0.4 and 5.75 m. Closer inshore, green becomes the most penetrating colour, the coefficients for all colours rising with the increased turbidity of the water.

In considering the variation of opacity with depth, one must remember the 'hardening' effect of absorption on polychromatic radiation, although this effect is greatly reduced by the use of colour filters. It is still probably of importance with the RG 1 red filter, as the longer wave-lengths of the range covered are absorbed even more rapidly than those near the 600 m μ limit. The effect is probably of much less importance with the green and blue filters.

Real variations of opacity with depth are often met with. As a general rule, ocean water becomes clearer below the surface layers, but inshore waters often show irregular variations, which may be very useful for studying their stratification. For exploring these rapid changes of opacity the use of Pettersson's transparency meter, which measures the intensity of a beam of artificial light reflected through 2 metres of water, is almost certainly preferable to the deduction of the opacity from the ratio of the daylight illuminations at two different depths, but it is not easy to correlate the results obtained by the two methods.

It is evidently highly desirable that oceanographers should be provided with a standardized method suitable for routine measurements of submarine daylight, and with this end in view the International Council for the Exploration of the Sea arranged for a special meeting of workers in the subject at the 1936 meeting at Copenhagen. It would seem that some further experience of the

available cells and modes of measurement is desirable before any definite specification of apparatus and methods can be drawn up. In the meantime, a fairly full review by different authors of the work done up to date, with extensive

bibliographies, will be found in the report of the 1936 meeting of the Council, and a report of the special sub-committee then appointed to consider the question is being presented at the meeting this month in Copenhagen.

Greenland Culture: (I) The Norsemen*

ACCOUNTS of the ill-fated Norse settlements in Greenland in medieval times, such as that recently published by Dr. Nörlund (see NATURE, 133, 949) have been based hitherto on the evidence afforded by the eastern settlement (now the district of Julianehaab), in which, thanks to the researches of the last fifty years, most problems of topography have been solved and the cultural history elucidated in no little detail by archaeological discovery. Of the western settlement, however, in the Godthaab District little was known either from literary sources or from archaeological investigation before the expeditions of the Commission for Scientific Research in Greenland, of which the results have been described recently by Dr. Aage Roussell. It was inferred, however, with reasonable certainty that the place now known as Kilaussarfik, visited by Daniel Brunn in 1904 and the site of Dr. Roussell's excavations in 1930, 1932 and 1934, was to be identified with Sandnes, and Ameralik Fjord with the ancient Lysufjördr, not least, perhaps, on account of the rarity of such a sandy formation on the rock-bound coast of Greenland. As, however, the area is being submerged rapidly, and the coast-line has changed considerably since the Middle Ages, this is by no means indisputable evidence.

Historical records relating to the west settlement are few. Apparently it was established simultaneously with, or just after, the east settlement, shortly before A.D. 1000. The Saga of Eirik the Red mentions a serious epidemic there in the first decade of the eleventh century. By the middle of the fourteenth century, Skraelings (Eskimo) had occupied all the west settlement, "so there are many horses, goats, cattle and sheep run wild, and no people, neither Christian nor heathen". All archaeological finds, in default of

evidence to the contrary, are to be regarded as prior to 1365.

In addition to the church at Sandnes and the neighbouring farm, of which the name is unknown, Dr. Roussell excavated in 1934 two other farm sites on the opposite side of the fjord. Of these, Umiviarssuk alone has been described, the important results obtained at Ujaragassuit still awaiting publication.

The site investigated at Sandnes included church and churchyard, house, smithy, and two large stable complexes. The store-house—invariably part of a Norse farm—presumably stood on the fjord bank, but, if so, it had been washed away. The central part of the farm had been built on sloping ground and a constant movement of soil has covered the whole site with midden, making it impossible to arrive at any accurate idea of stratification. At times, objects were found above others which obviously were of later date.

Since the date of Daniel Brunn's visit, the church ruins at Sandnes have suffered much damage owing to submergence and climatic conditions. Consequently it was found impossible to determine the extent of the churchyard; but accumulations of stones on the fjord beach indicate the probable limit of interment. Only in the westerly part of the churchyard were interments uncovered.

No less than forty-two burials were found huddled in a confined space. They lay under the midden in coarse yellow gravel and only just below the original surface. Owing to crowding, older graves frequently had been disturbed in digging new, and half skeletons, or skeletons with lower limbs hewn off, were found. As is usual in Christian burials, the body lay on the back with the head towards the west and arms crossed on the breast. One interment in the south end of the area contained two adults, presumably man and wife, with the skeleton of a child lying on each. Alongside and evidently buried at the same time lay a fifth skeleton, not fully grown, and beside the skeletons was a small crudely fashioned wooden cross, the only piece of grave furniture found *in situ*. It may be presumed that these five burials were the result of an epidemic, such as is mentioned in the sagas of Eirik and Thorfinn.

* Researches into Norse Culture in Greenland—Sandnes and the Neighbouring Farms. By Aage Roussell. Appendix: Greenland Runic Inscriptions, 4. (Meddelelser om Grønland, Bind 88, Nr. 2.) Pp. 223+6 plates. 11.00 kr.

Researches into Norse Culture in Greenland—Animal Remains from the West Settlement in Greenland, with Special Reference to Livestock. By Magnus Degerbøl. (Meddelelser om Grønland, Bind 88, Nr. 3.) Pp. 55+1 plate. 2.50 kr.

Researches into Norse Culture in Greenland—Evidence of Iron Extraction at Sandnes, in Greenland's West Settlement. By Nels Nielsen. (Meddelelser om Grønland, Bind 88, Nr. 4.) Pp. 14+1 plate. 0.75 kr.

(København: C. A. Reitzels Forlag, 1936.)

What was from the artistic point of view the most important find made in the course of this investigation may be mentioned here, as it came from the churchyard, though not found *in situ*. This was a carved slab of wood of unknown use, though it may have been part of the cover of a pyx. The wood has been identified as fir and driftwood. On it is carved in relief a representation of the Crucifixion showing the figures of the Virgin Mary and St. John in a pose and with attributes characteristic of medieval Scandinavian art. The figures are Gothic; but the ornament is still Romanesque. Though unquestionably of Scandinavian origin, it is not of local workmanship, and may derive from thirteenth century Iceland, or possibly Norway. Examples of local workmanship are to be seen in representations of the Crucifixion, rough in character, in which the figures in metal had been nailed on in a technique familiar in examples known from Iceland.

The important site at Umiviarssuk afforded fuller detail than Sandnes of the cultural level of the Norse farm, though here in the excavation of the house itself the work of clearing the plan was complicated by the fact that a later building overlay one and possibly two earlier structures. The farm buildings of the west settlement were substantial erections of stone. It was possible to ascertain the disposition of living rooms, sleeping rooms, hearths, etc. Immediately behind the farm-buildings at Sandnes was a series, or rather two complexes, of outbuildings for cattle, sheep, pigs, and goats and the farm workshop. In one of these, stone divisions provided 'boxes' for tethering the cattle; while in another, small finds suggested that one or more of the humbler female servants had slept here. Sandnes also had a small forge, which afforded samples of the iron used in working.

An interesting building at Umiviarssuk was a bath house, which, though the bath is frequently mentioned in the records, is the first to be found in Greenland. It is of the usual vapour-bath type, with furnace and shelves, on which the bathers reclined. It was apart from the house, and if the bathers did not follow the modern practice in high latitudes of a cold plunge in the snow, they at least had to pass through the cold air in returning to the house. Another find on this site of an unusual character was a movable bed. Although there are references to such beds in the sagas, its use had died out in the Middle Ages in favour of the bed fixed to the wall. It was not reintroduced until the sixteenth century; but its survival in Greenland points to the backward state of the community.

The most noteworthy feature in the work of Dr. Russell's expeditions is the very large number

of small objects found, which has thrown a flood of fresh light on Norse culture in Greenland. The character of the soil enabled the preservation of a number of objects, especially in wood, bone and baleen, which had perished on sites previously excavated. Nearly twelve hundred objects in all were found. The state of preservation may be judged from the fact that in some the original colour of the wood can still be discerned. Among the small objects, one of the most interesting is a toy model of a boat, which reproduces its original in accurate detail. Comparison with earlier known examples of the Norse boat dating from the sixth century shows that the form of ship virtually suffered no change over a period of six hundred years.

Other finds included tools, weapons, implements, household utensils, clothes, games such as chess, dice and draughts, toys and objects of unknown use. Trinkets were rare. In addition to the objects of art already mentioned—the wood-carvings of a religious character—there was a number of small objects in bone, wood and ivory, including two lively representations of animals, a bear and a walrus, and two of the human face, of which one in walrus ivory with its wide mouth, long upper lip, heavy jaw and coarse skin gives anything but a favourable impression of the physical type of some, at least, of the Greenlanders.

The animal bones indicate that the inhabitants of the western settlement kept cows, sheep, horses, pigs and dogs and hunted the same wild animals, reindeer, seals, whales, arctic foxes, arctic hares, and polar bears, as the settlers on the east coast. For the first time, the bones of the dog are available for comparison with representations of the animal of this period. The surprising feature is the length and slenderness of the legs, which suggest a breed of something of the greyhound type.

Although there is evidence to suggest that the Norsemen had extracted iron in Greenland, the number of iron objects found is small. The material from Sandnes is the most considerable find that has been made, consisting of fifty lumps of slag and a small piece of hammered iron of prismatic form. The material has been subjected to detailed examination and is very heterogeneous. Two types of iron are present, which agree with what is known of Middle Age practice of producing iron in hearth pits, and shows the difficulty experienced by the ancients in producing iron capable of hardening. While some samples consist of a soft iron, practically devoid of carbon, others are a medium hard carbon steel. The evidence from Sandnes is taken to show that the Norsemen did produce a form of steel, but that their methods of working and exposure to the air reduced the product finally to nothing but a soft iron.

Belgian Stratosphere Balloon Experiment

THE most difficult part of the planning of a large stratospheric balloon is how to control the rate of descent in the upper atmosphere. If a balloon is large enough to reach about 19 miles (1/100 atmosphere) the hydrogen must contract during the descent, and the bag will be only 10 per cent filled at 10 miles: it is then difficult to avoid a dangerous flapping of the bag, except by controlling the speed by a continuous dropping of ballast; incidentally, the weight of that extra ballast would have reduced the maximum altitude reached.

If air is allowed to flow into the bag through

long as before, and about twenty times as heavy, which weight is prohibitive. To calculate the minimum diameter admissible, it is necessary to know exactly the amount of heating inside the bag due to the sun. As it depends on the thermal air eddies inside and outside the bag, it is useless to try to determine that quantity by extrapolation from experiments made on models a few feet in diameter. In order to measure the heat transfer on a model as large as possible, an experimental ascent was planned by A. Piccard and M. Cosyns with the old *F.N.R.S.* filled with hot air. At an

altitude of about 5 miles, the heating power of the sun is not very far from its maximum value, and the temperature is about the same as at 20 miles. Knowing the total weight of the balloon, and the amount of supplementary heat necessary to balance it, the temperature rise due to the sun could be deduced with a precision of a few tenths of a degree.

The supplementary calories were to be furnished by a burner placed inside the bag (Fig. 1b) using pure propane, 150 lb. of which was carried in the liquid state in an aluminium bottle weighing 60 lb. The burner was able to burn 2 lb. of propane each minute, with good efficiency, and twice as much in emergency (the

Fig. 1.

the appendix, the flapping danger disappears; but, during the daytime, the sun heating the air in the bag causes sufficient expansion to stop the descent, even if all the hydrogen is removed. A better solution seems to be to admit air, but to remove it automatically as soon as it is warmed. That method was tested by Max Cosyns during his 1934 ascent, by replacing the valve of his balloon by a collapsible fabric tube, about six feet in diameter, distended by wooden rings, and stretching down the axis of the balloon (Fig. 1a). If the opening of that tube is set near the limit between the hydrogen and the air, the air flows continuously upwards as soon as it is warmed. The method worked perfectly well on the *F.N.R.S.*, the diameter of which was 100 ft.

For a 200-ft. balloon, the use of the same principle would require a tube 17 ft. in diameter, twice as

lifting power given by a pound of propane is about 160 lb.). It was composed by 42 batwing-burners placed on a ring 7 ft. in diameter, to ensure a good mixture of hot and cold air, and to prevent a flow of gases at too high a temperature from reaching the top of the balloon. The flow of propane was measured by a diaphragm 'déprimomètre,' and by weighing at intervals the aluminium bottle.

Unfortunately, just before starting on May 25, the twisting of some ropes obliged the land crew to release some of the slings, and an unforeseen squall shook violently the bottom of the balloon, upturning the burner before it was possible to shut off the flame; the bag of the balloon was destroyed by fire in about a minute. The material loss was not important, as the *F.N.R.S.* was getting old and was about to be dismantled.

M. COSYNS.

News and Views

Prof. F. W. Thomas, C.I.E.

PROF. F. W. THOMAS of Oxford has been elected president of the ninth All-India Oriental Conference, which will be held at Trivandrum in December next. He has also been elected a corresponding fellow of the Philosophical and Historical Section of the Prussian Academy of Sciences. Prof. Thomas, who has been Boden professor of Sanskrit in the University of Oxford since 1927, and is a fellow of Balliol College, was librarian of the India Office from 1903 until 1927, and was awarded the C.I.E. in the honours list of 1928 on his retirement from that office. He is chairman of the Section of Oriental Studies of the British Academy, and represents that body as a governor of the School of Oriental Studies of the University of London. He is also reader in Tibetan and lecturer in comparative philology in the University of London. Prof. Thomas has long been known as one of the foremost scholars in the classical languages of the East, in which he has acted as examiner not only in all the universities in Great Britain which offer a course in those languages, but also in the principal universities of India. His outstanding knowledge of Buddhist art and literature received the signal recognition of the award of a medal in 1934 at the Tokyo celebration of the two thousandth anniversary of the birth of Buddha. He is the author of a large number of publications on the philology and literature of Sanskrit, Pali and other oriental languages, as well as on the art and literature of Buddhism.

Prof. Walter G. Cady

THE Council of the Physical Society has awarded the fourteenth Duddell Medal to Walter G. Cady, professor of physics at the Wesleyan University, Middletown, Connecticut, U.S.A., for his work on piezo-electric resonators and oscillators as standards of frequency. Prof. Cady's pioneer work on the subject was published in 1922 (*Proc. Inst. Radio Eng.*, 10, 83) and the value of the device may be judged from the fact that it stimulated research work on the subject in all parts of the world, more than a thousand papers having been published on the properties of piezo-electric crystals since the appearance of Cady's first paper. Of course, these are not all due to Cady's work, for Langevin had previously used piezo-electric crystals as vibrators for underwater signalling, but Cady's particular contribution—the use of the quartz resonator as a standard of time or frequency—has quite obviously inspired most of the work. The use of these resonators as standard vibrators has made it possible to measure frequency and intervals of time with an accuracy not previously attained. It is scarcely necessary to emphasize the importance to physics of increased accuracy in such fundamental measurements. Among the applications which have already been made the following may be

mentioned: (1) The quartz-clock now used as standard in some observatories. It is in some respects superior to the pendulum clocks, and in any event is a most valuable supplement to them. (2) The measurement and control of the frequency of alternating currents in connexion with measurements of dielectric constant, 'absolute' electrical measurements, etc. (3) The measurement of the velocity of ultrasonic sound waves. Duddell, who was responsible for so much elegant instrumental work, would have been the first to recognize the beauty of Prof. Cady's device, and it will be a source of great satisfaction to all scientific workers to know that the value of Prof. Cady's work has been recognized in such an appropriate manner.

Centenary of the University of Durham

THE University of Durham, though now well over a hundred years old, has just celebrated its centenary. It was originally intended to hold the celebrations five years ago, since the Act of Parliament which provided for the foundation was passed in 1832. Owing to the economic depression, however, it was felt inappropriate to enter into rejoicings under the cloud of industrial stagnation which, in 1932, was locally responsible for widespread distress. The present year has a historical claim to recognition, apart from the atmosphere of returning prosperity, for it was in 1837 that the University was granted its charter by William IV. Moreover, as a result of the recent Royal Commission, the University is about to enter upon a new phase of its history. The main celebrations were held at Durham on July 1, and were attended by delegates from all the other Universities of the British Isles and from several in Canada, Australia, New Zealand, South Africa, India and the United States. Learned societies were represented by, among others, Sir William Bragg, Lord Dawson of Penn, Dr. H. Spencer Jones, Prof. F. G. Donnan and Prof. O. T. Jones. After a morning visit to the Colleges, including the Castle, a centenary service was held in the Cathedral, where the preacher was the Bishop of Durham. The keynote of Dr. Henson's discourse was that universities are the "watchdogs of human liberty". "The new universities," he said, "were born and cradled in an atmosphere of freedom. They surely must stand in the forefront of the championing of academic liberty against the aggressions of the totalitarian State or the subtler assaults of racial fanaticism". After the service, the delegates were entertained to luncheon, some in the Great Hall of the Castle (by the University), and others at the Town Hall (by Lord Londonderry, Chancellor of the University and Mayor of Durham).

In the afternoon, a Centenary Convocation was staged in the picturesque surroundings of the Castle quadrangle. Each delegate was introduced to the

Chancellor, to whom addresses of congratulation were presented. The Chancellor then conferred the honorary degree of D.C.L. upon nine distinguished men: Dr. C. A. Allington, Dean of Durham; Prof. P. P. Bedson, emeritus professor of chemistry; Lord Cadman, an old graduate of the University; the Hon. J. A. Hanan, chancellor of the University of New Zealand; Sir John Jarvis, the promoter of many schemes to help the distressed area of Jarrow; the Rev. S. R. P. Mouldsdales, until recently principal of St. Chad's College; Mr. Tracy Philipps, explorer and war correspondent; Sir Cuthbert Wallace, president of the Royal College of Surgeons; and Mr. G. H. A. Wilson, master of Clare College and vice-chancellor of the University of Cambridge. Convocation was followed by a garden party in the adjoining Fellows' Garden. Later, the delegates were entertained to a banquet in the Great Hall, after which they were received by the Council of the Durham Colleges.

It is interesting to record that so early as 1650 a petition to Parliament that a college be established at Durham was approved by Cromwell. When university powers were applied for, however, the proposal was thought to be prejudicial to the older universities and the Great Seal was withheld. No more was heard of a northern university until a draft scheme was drawn up in 1831. The necessary Act was passed in 1832, and the first students came into residence during the following year. Among the first members of staff was J. F. W. Johnstone, lecturer in chemistry and mineralogy. About the same time (1834) the Newcastle-upon-Tyne College of Medicine originated, though it did not become connected with the University of Durham until 1852. Durham College of Physical Science was founded in Newcastle in 1871. It had then four professors—mathematics, physics, chemistry and geology—but by the time its name was changed to Armstrong College, in 1904, a very wide range of university subjects had long been incorporated. Now, both the College of Medicine and Armstrong College are about to be united, under the revised constitution of the University, as a new corporate body to be known henceforth as King's College. At Durham itself, science seems to have lapsed after the death of Johnstone in 1855. Since 1924, however, when the first block of the present Science Laboratories was opened, several very flourishing schools have developed. Under the new regime, the University of Durham (consisting of the Durham Colleges, together with King's College, Newcastle-upon-Tyne) enters the most promising period of its history, with every prospect of expanding achievement and prosperity.

The World's Air Altitude Record

THE world's air altitude record was regained for Great Britain by the Royal Air Force on June 30, by a flight to an altitude of 53,937 feet (more than ten miles). The previous record of 51,362 feet was held by Lieut.-Colonel Mario Pezzi for Italy, who beat the then British record of 49,944 feet last autumn. The flight was made from the aerodrome

of the Royal Aircraft Establishment, Farnborough, by Flight-Lieut. M. J. Adam, using the Bristol 188 experimental high altitude aircraft. This was the same machine as used by Flight-Lieut. Swain, R.A.F., for the previous record, but was fitted with a special Bristol Pegasus engine. It had various detail improvements as suggested by experience. The pilot wore the actual high-pressure suit that was prepared as a reserve for the previous record flight, with small improvements. These included precautions against 'frosting up' of the Celestroid windows of the headpiece, and an emergency breathing pipe to lead air direct from the outside when necessary, instead of having to slash open the front of the headpiece as did Flight-Lieut. Swain, upon landing, after his flight. The transparent material forming the cabin roof was observed to crack upon reaching an altitude of about 48,000 feet, but this was not serious enough to interfere with the continuation of the flight.

THE ascent was made in 1 hr. 35 min., and the total time of the flight was 2 hr. 15 min. The minimum pressure and temperature were 77.8 mm. of mercury and -48.9°C . respectively, both occurring at the maximum height. The pilot experienced a good deal of navigational trouble due to cloud-layers at intervals, at one time being forced to fly east, facing the sun, which at 6 a.m. was low enough to blind him. A steady north-westerly wind, estimated by the pilot to be of about 100 miles an hour velocity, was encountered in the upper regions. It is understood that the aircraft will continue to be employed upon researches into conditions of flight in the upper atmosphere.

Atlantic Air Mail Service

THE first test flight of the Atlantic air mail service began on July 5 when the Imperial Airways flying-boat *Caledonia* left Foynes, Ireland, for Botwood, Newfoundland, and two and a half hours later the Pan-American Airways *Clipper III* took off from Botwood on the easterly crossing. The two boats alighted at their destinations within a quarter of an hour of each other on July 8. The *Caledonia*, under Captain A. S. Wilcockson, flew mostly at a height of 1,500 ft. to avoid the worst of the head-wind; she followed a rhumb line course at an average speed of about 132 miles an hour and was in the air for 15 hr. 28 min. The *Clipper III*, under Captain H. Gray, flew most of the way at 10,000 ft. to make the most of the following westerly wind; she kept roughly to a great circle course and her average speed was 156 miles per hour and flying time 12 hr. 37 min. Both commanders described the crossing as comparatively uneventful, and paid high tribute to the work of the wireless stations on both sides of the Atlantic in assisting their navigation.

Centenary of the General Register Office

AN exhibition which opened on July 1 at the General Register Office, Somerset House, Strand, London, W.C.2, for a duration to be announced later,

marks the centenary of the establishment of the general registration of births, deaths, and marriages in England and Wales, by illustrating the work of the Office, as well as the character of the records which are in its charge. Although the system of civil registration was established only one hundred years ago, its origins in England go back no less than four hundred years. Such statistical material relating to the population, outside the parochial records, as was recorded before 1837 was transferred to the custody of the Registrar General under the Marriage and Registration Acts of 1836. The earliest form of record, the parochial register of baptisms, marriages and burials, was established by Thomas Cromwell in 1538; but so long ago as the sixteenth century the value of demographic data and the inadequacy of the parochial system for this purpose were appreciated.

In 1590, Lord Burleigh put forward a proposal for the establishment of an office for a general register to summarize "how many christenings, weddings and burials were every year in England and Wales". The proposal was not adopted; and subsequent attempts to secure some measure of systematic collection of facts were both unsatisfactory in working and incomplete, owing to increase in the number of nonconformists, who did not avail themselves of the services of the parish church. It was owing to this latter factor that the earliest records now preserved at Somerset House are those which did not come within the established order, belonging to the refugee churches of Walloons and French, the Chapels Royal, the Independents, and the Society of Friends of the sixteenth and seventeenth centuries. It is interesting to note that the last-named body, with characteristic precision, was the first to register births and deaths, rather than baptisms and burials. The official guide to the exhibition ("The Story of the General Register Office and its Origins from 1538 to 1937". Pp. 30+6 plates. London: H.M.S.O. 6d.) deals with these and other matters of much sociological interest, especially in the light thrown by the registers on the early history of nonconformity and the scandalous 'Fleet' marriages.

Ethnological Museums: Methods and Limitations

DR. H. S. HARRISON, in his presidential address to the Royal Anthropological Institute delivered on June 29, played the part of a wandering sceptic, to use his own term, to excellent effect in setting out some of the more striking shortcomings of the ethnological museum as a place of exhibition of material objects bearing on man's cultural development. As he pointed out, there is a considerable body of exhibits, such as, for example, musical instruments, personal ornaments, money and currency, which find their place in a museum as 'material objects', but of which the real significance is non-material and is lost on either the distributional or comparative method of arrangement, as their interest lies not in form or material, but in their sociological functions and meanings. Practical considerations limit the use of labels, quite apart from the danger of the museum

becoming what Dr. Harrison said has been described as a collection of labels illustrated by exhibits. Dr. Harrison also showed himself a keen but kindly critic of the evolutionary method of display, pointing out its weaknesses in the scanty evidence and uncertainties relating to origins, the necessary, but at times excessive dependence upon inference, and the ambiguities of direction, including the possibility of degeneracy. Among the instances quoted in support of the argument he cited an interesting example in the uncertain development of the canoe and the relation of the plank and dug-out forms.

With a sympathy born of experience, Dr. Harrison recognizes the limitations imposed by space on experiment to meet defects inherent in present museum methods, but hopes for their alleviation in a National Anthropological Museum, which would be sufficiently spacious and catholic to deal with such problems. Notwithstanding his criticisms, as a museum man himself he believes firmly in the importance of the museum as a technological laboratory, forming an essential part in a school of ethnology. While anthropologists will warmly endorse his plea for a national anthropological museum, they will trust that his anticipation of its foundation before the close of the present century is a playful euphemism for "at no distant date".

Proposed Rhodes-Livingstone Memorial

To mark the jubilee of the foundation of the two Rhodesias by Cecil Rhodes in 1890 and the centenary of the setting out of David Livingstone for Africa in 1840, it is proposed to found a Rhodes-Livingstone Institute for Central African Studies in Northern Rhodesia. The main purpose of the Institute will be the study of the effect on native African society of the impact of European civilization and the urgent problem of establishing permanent and satisfactory relations between native and non-native. The proposal has the support of the Archbishops of Canterbury and York, the Right Hon. W. G. A. Ormsby-Gore, Lord Lugard, Lord Hailey, Dr. Henry Balfour, Sir William Bragg and others. It is proposed to purchase at a cost of £15,000 the premises now housing the Museum at Livingstone, the old capital of Northern Rhodesia, with the adjoining old Government House. The Museum contains objects of historical interest relating to David Livingstone and the nucleus of an important ethnographical collection. It was formed by the Government of Northern Rhodesia with assistance from the Beit Railway Trust, the Royal Geographical Society, the Scottish National Memorial at Blantyre and a number of individual benefactors. The premises will be vested in a trust, which will be responsible for administration and financial control. As a preliminary to the foundation of the Institute and the incorporation in it of the existing Museum, the Government of Northern Rhodesia has appointed an expert in applied anthropology, to whom an assistant will be added later if funds permit. Although the Rhodesian Government will bear its full share of the cost, an

appeal is made for contributions towards the capital cost of the Institute and the endowment of the Trust to enable admirers of Livingstone and Rhodes to give material expression of their interest in them and the future of the country with which they were connected. Contributions may be directed to any branch of Barclay's Bank or the Standard Bank of South Africa.

British School of Archaeology at Athens, 1935-36

IN accordance with the new arrangement for the publication of the "Annual of the British School of Archaeology at Athens", the formal matter, which includes the report of the director covering the activities of members of the School during the year, the accounts, and the summary of archaeological operations in the Greek area of the eastern Mediterranean in the preceding year, will in future be issued separately to subscribers, the report for the session 1935-36 being the first occasion on which the decision of the Committee takes effect. In the chronicle of the session precedence is taken by a reference to the lamented and untimely death of the director, Mr. Humphrey Payne, on May 9, 1936. Mr. A. H. G. Megaw, who took charge of the School as acting director, left in the following July to take up his duties on appointment as director of antiquities in Cyprus. Owing to the temporary closing of the British School of Archaeology at Rome, a number of its students worked in the School at Athens. Excavations by members of the School were carried on at Monasteri in the Perachora, at Siphnos and at Trapeza in eastern Crete. Miss W. Lamb excavated at Kusura in Anatolia. Supplementary excavations in the Heraeum of Perachora, which had been planned by Mr. Payne, were postponed until the following season. The manuscript of the account of the excavation of this important site was left in an advanced state by the late director, and it is anticipated that publication of the first volume will not be long delayed. In the chief descriptive notes of the activities of the School reference is made to some interesting discoveries in Crete. Although no further investigation of the Roman villa was possible, surface finds east of the basilica indicate that this was an important residential quarter of the Roman town in the first and second century A.D.

Speleological Conference at Bristol

FURTHER particulars of the second annual conference of the British Speleological Association to be held at Bristol on July 23-26 next (see NATURE, May 29, p. 919) are now available in the advance programme which has been issued. Through the hospitality of the University of Bristol the conference and exhibition will be held in the Great Hall of the University. The exhibition will include contributions from nearly all the important caves in the world, as well as some unique illuminated transparent photographs. Probably the largest and most valuable collection of 'Blue John' will be exhibited. On the evening of July 24 an illustrated public lecture will be delivered by the Abbé Breuil on some aspects of the

French and Spanish caves. Among the lectures announced is a brief account by Mr. C. R. Hewer of some of the caves to be visited on the Continental tour on July 27-August 7 when members will have the opportunity of visiting caves not as a rule accessible to the public. At Nurnberg, after a visit to the Museum for Prehistory, the party will proceed to Teufelshöhle, Maximiliansgrotte, and other caves of archaeological, geological and palaeontological importance at Pottenstein, where also a mesolithic cave shelter has been especially excavated for the visit by the "Gaukulturamt". At Brno, Czechoslovakia, Prof. C. Absolon will conduct the party over the Museum, with its unique collection of archaeological finds from the Moravian caves, which include remarkable examples of palaeolithic plastic art; and in the afternoon of the same day the caves, which are the centre of the great mammoth hunters' culture of Moravia, will be visited. Passing through Vienna the party will proceed to the famous 'Drachenhöhle' from Mixnitz, the Lower Lurhöhle from Peggau and the Eisriesenwelt—ice cave from Werfen, the last place of call being Salzburg.

The Swiss Society of Natural Sciences

THE recent issue of the *Verhandlungen der Schweizerischen Naturforschenden Gesellschaft* contains an account of the annual meeting of the Society held at Solothurn in August 1936 and also reports of the work of the previous year. The object of the Society is to promote the study of all branches of natural science in Switzerland. Between the annual meetings for the presentation and discussion of papers, the work of the Society is carried on by a number of commissions. Some of these are concerned with the administration of endowments, while others undertake field work in various sciences. The latter are financed partly from members' subscriptions, but mainly from Government grants. Among the commissions performing work of national importance is the Geological Commission, which is engaged in the publication of a geological survey of Switzerland on scales of 1 : 25,000 and 1 : 200,000. In addition to the purely scientific commissions, there is a Commission for the Preservation of Nature, which is doing valuable work in preserving sites of scientific interest or scenic beauty, as well as in promoting legislation for the protection of forms of wild life which are in danger of extermination. Besides administering Government research grants, the Society also acts as the official representative of Switzerland on international scientific unions, and the volume under notice contains the reports of the Swiss delegations to a number of such unions.

THE presidential address at the annual meeting in 1936 was given by Dr. Karl Dandliker, who took as his subject, "Birth-Rate Decline and Surplus". He showed how, in spite of the excess of births over deaths, the population of many countries in Europe is bound to decrease before long. A paper was read by H. Brockmann on "Swiss Farm-Houses", in which two types of buildings were distinguished: one type

has evolved from the use, by primitive man, of caves as shelters, while the other has evolved from tree shelters. Other papers read before the general meeting were "Inheritance by Labile Genes", by A. Ernst; "The Sting of the Bee", by M. Rooh; "Ontogenesis of the Bird as a Problem in Evolution", by A. Portmann. These papers are all printed in full. In addition, abstracts are given of some 150 more specialized papers, dealing with nearly all branches of science, which were presented to the sectional meetings of the Society.

Royal Cornwall Polytechnic Society

THE one hundred and third annual report of the Royal Cornwall Polytechnic Society, besides containing the usual list of members, financial statements and an account of the work of the Falmouth Observatory, has several contributions of general interest. One of these is by Miss R. Beckett, who, in a paper on "Public Library Service", traces the growth of public libraries due to the Library Acts of 1850, 1855 and 1919. The Act of 1850 limited the rate to be levied to $\frac{1}{4}$ d. in the £ and that of 1855 to 1d. These sums proved quite inadequate, but it was not until 1919 that the penny rate limitation was abolished. In practice to-day, the average expenditure is 1s. 4d. per head of population, though some authorities expend as much as 2s. 6d. In another contribution, Mr. S. Furze deals at length with the operations involved and the machinery used in tin dressing, while in a third, Mr. J. H. Rowe gives the early history of Hayle Foundry, which was founded by John Harvey (1730-1803) and developed by his son Henry Harvey (1775-1850). This foundry was the earliest in Cornwall, and became ultimately the most important engineering works in the west of England. The well-known engineer Arthur Woolf (1766-1837), the pioneer of the compound steam engine, was at one time superintendent of this works, and it was there that he built some of the finest Cornish pumping engines of the time. The history of the Royal Cornwall Polytechnic Society inevitably recalls the Fox family, and the report has a tribute to Mr. Wilson Lloyd Fox, who died on February 10, 1936. He gained one of the Society's prizes in 1860, became a member in 1865, served as president in 1922-24, and was secretary of the Committee of the Falmouth Observatory from 1877 until 1931.

Intelligence, Character-training and Civilization

A LUDWIG MOND LECTURE entitled "Intelligence and Civilization", delivered at the University of Manchester last October by Prof. G. H. Thomson, of the University of Edinburgh, has been published in the first issue of the new *Journal of the University of Manchester*. After a preliminary discussion of some aspects of recent researches in the field of intelligence measurements, Prof. Thomson proclaims his belief (which was also H. T. Buckle's) that the history of the advance of civilization has been the history of the conquest of the world by intelligence. He preaches the salvaging of civilization "through the cultivation by an education proper to each of

the intelligence of all". Of character-training he is profoundly distrustful. A clear vision of truth is, he assumes, to be attained solely through cultivation of the intelligence and "the schoolmaster's sole business is to lead his pupils to see truth clearly . . . and . . . that is the only character-training the school may lend itself to, if it is to refrain from serving party or class . . . but is to serve civilization". He does not think much of civilization's debt to the poets ("far more dangerous than scientists"), notwithstanding that he holds intelligence to be based on imagination, and he makes a point of registering disagreement with Earl Baldwin's hope, confided to the Congress of Universities of the Empire, that from those universities may presently come forth "poets who will inspire Europe and the world once more with a sense of unity and a sense of freedom".

The Utilization of Wood as Fuel for Motive Power

IN the *Bulletin* of the 'Société d'encouragement pour l'Industrie Nationale' of January is printed an abstract of a paper by R. Vaultrin on the utilization of wood as fuel for motive power. Towards the end of the Great War, the French Ministry of Inventions made experiments on carrying heavy loads between Paris and Rouen by motor-lorries provided with suitable gas generators using wood for fuel, but the results obtained were not good. In 1928, after a further rally with 'camions à gazogène', the problem was completely solved; but at that time the price of the wood fuel was too high to make it profitable. A notable rally was made in 1930 between Paris and Rome, crossing the Alps and the Apennines, and another was made through the Landes where resinous fuel was used and found suitable. Recent results for tourist vehicles gave 50 miles per hour consuming about 70 lb. of firewood, costing six francs for a sixty miles run. Heavy motor-lorries can run at 30 miles per hour, the cost for sixty miles being fifteen francs. In France, there is an annual over-production of thirteen million cubic yards of firewood. This would be sufficient for 60,000 motor-vehicles using gas generators. At the moment, the difficulty is to obtain, on the road, supplies of suitable wood with constant humidity. This double problem has been solved between Frankfurt and Cologne. In France there are already large stores on a 'national' road, and all the main routes on the east are being supplied with stores. The control of the humidity of the wood distributed is being studied.

Electric Furnaces

DURING last year the use of electricity for the melting and heat treatment of iron and steel in Great Britain considerably increased. There has been a revival in the demand for arc furnaces, a number of which, varying in capacity from 500 to 6,000 kilowatts, are being installed. In the *Electrical Review* of April, Mr. D. Campbell states that the furnaces ordered from a single manufacturing company during last year would consume about a 100 million electric units a year. The cost of the annual power bill for these furnaces alone would be about £200,000. A

furnace of 6,000 kilowatt capacity, probably the largest electric melting unit in Europe, has just begun operation in Sheffield. Within its small area of furnace hearth (13 ft. diameter), as much energy is consumed per day as the aggregate loads of Cambridge, Salisbury and Tonbridge. Unfortunately, the requirements of larger and interconnected power stations make it essential to install higher rupturing capacity switch-gear, and this constitutes a heavy charge on small firms which may want to use electric furnaces. Seeing that the cost of the energy consumed by the furnace during its average life (ten years) is about thirty times the original cost of the complete installation, the companies should offer attractive conditions to steel manufacturers. The extreme purity of arc furnace steel owing to the absence of slag inclusions is now generally recognized, and for many types of forging this steel is specified. The choice between high-frequency furnaces and arc furnaces is difficult to make. Although the capital expenditure for high-frequency furnaces is much higher, yet when melting operations only are required they are cheaper to work.

Astronomy in Japan

THE Kyoto Imperial University has accepted a donation equivalent to about £10,000 from the Osaka Electric Railway Co. towards the building of an observatory on the southern peak of Ikomasan at a height of 640 metres. The observatory will include a main building with a 9-metre dome, a solar laboratory, housing for a reflector and a dormitory. The equipment of the solar department of the Kwasan Observatory is to be transferred to this new site, in addition to other instruments including the 80-cm. Tomkins reflector. Later a large museum devoted to astronomical exhibits and those of allied sciences will be built near the Ikomasan Observatory. Prof. Yamamoto will be the director of the group. The Kwasan Observatory will then become a purely academic institution. The Osaka Municipal Electric Museum, which has recently been completed, includes a Zeiss planetarium, which is installed under an 18-metre dome on the sixth floor of the Museum. *Bulletin* No. 326 of the Kwasan Observatory directs attention to a daily series of sun-spot observations made for fourteen years by Mr. Katue Misawa, whose failing eyesight now prevents the series from being carried on. The observations, which have been made regularly under excellent weather conditions, have been of great use in supplying data with the minimum delay to Japanese investigators. Observations of the zodiacal light are receiving special attention in Japan, and it is planned to establish a special observatory at Onomiti, Hiroshima-Ken, at a height of 150 metres. The observed longitude of the Kwasan Observatory, deduced from 74 observations made with the 90 mm. Bamberg transit in conjunction with the reception of Greenwich wireless time signals, is $-9^{\text{h}} 3^{\text{m}} 10.815^{\text{s}} \pm 0.002^{\text{s}}$ or E. $135^{\circ} 47' 34.72'' \pm 0.03''$. The elements of latitude variation for the epoch 1934.0-1935.9 computed by Dr. Kimura from data provided by five northern stations are given in *Bulletin* No. 322.

Hygiene in the Bacon Factory

WITH this title, *Bull.* No. 1, published by the Bacon Development Board, Thames House, London, S.W.1 (1s.), lays down certain standards of sanitation as a condition of every licence to produce bacon, and describes in some detail a system of sanitation which, if adhered to, will assist curers to comply with the conditions of their licence, and help them, in their own interests, to reduce the risk of spoilage of their products. The construction, maintenance and equipment of the factory are first discussed, after which the daily and the periodical cleaning of the premises are described. Next, the keeping of the meat and bacon clean and wholesome, and the personal hygiene of the employees are dealt with. Data are given in an appendix upon sources and reduction of contamination and the use of sodium hypochlorite as a disinfecting agent.

Brown-Firth Research Laboratories

A BROCHURE of some seventy pages deals with the equipment and work of the Brown-Firth Research Laboratories in Sheffield. The various types of research undertaken are described briefly, and the apparatus used is illustrated. A long list of original papers which have been published is appended, together with a catalogue of books, manuscripts and reports available in the library. To all who are concerned in any way with the development of modern steels, this publication cannot fail to be of interest.

1851 Exhibition Studentships and Scholarships

THE science scholarship committee of the Royal Commission for the Exhibition of 1851 has recently awarded the following senior studentships and overseas scholarships, upon the recommendations of the universities and other institutions named: **SENIOR STUDENTS.** Dr. H. J. Bhabha (University of Cambridge), for research in theoretical physics at Cambridge; Dr. H. N. Rydon (Imperial College of Science and Technology), for research in organic chemistry at Oxford; Dr. J. L. Harley (University of Oxford), for research in mycology at Oxford; Dr. A. H. S. Holbourn (University of Oxford), for research in experimental physics at Oxford. A fifth Studentship was given to Dr. T. S. Westoll, who was a palaeontologist recommended by University College, London, but he has been appointed to a lectureship at Aberdeen and therefore will not take up the award. **OVERSEAS SCHOLARSHIPS.** *Canada:* Mr. A. J. C. Wilson (Dalhousie University, Halifax), for research in physics at the Massachusetts Institute of Technology and the University of Cambridge; Mr. D. M. Roes (Dalhousie University, Halifax), for research in experimental zoology at the University of Cambridge; Dr. H. Rudoff (McGill University, Montreal), for research in organic chemistry at the University of Oxford; Dr. J. L. Morrison (McGill University, Montreal), for research in physical chemistry at the University of Cambridge; Mr. A. G. Ward (Queen's University, Kingston), for research in physics at the University of Cambridge. *Australia:* Mr. R. D. Hill (University of Melbourne), for research in physics at

the University of Cambridge; Miss K. L. Prendergast (University of Western Australia), for research in palaeontology at the University of Cambridge. *New Zealand*: Mr. I. Lander (University of New Zealand), for research in physical chemistry at the University of Manchester. *South Africa*: Mr. F. Sebba (University of Cape Town), for research in inorganic chemistry at the Imperial College of Science and Technology. *Irish Free State*: Mr. D. A. Webb (Trinity College, Dublin), for research in zoology at the University of Cambridge; *India*: Mr. N. S. Nagendra Nath (Indian Institute of Science, Bangalore), for research in theoretical physics at the University of Cambridge.

THIS is the first occasion on which a scholar from India has been included in the Overseas scheme of the Royal Commission for the Exhibition of 1851: and the award of the scholarship has been made possible by the action of H.M. Treasury in extinguishing the balance of the liability for contributions to the cost of new buildings for the Science Museum. The following preliminary selection committee was appointed by the Government of India to sift applications in India for the scholarship: Mr. J. E. Parkinson, Educational Commissioner with the Government of India (chairman); Dr. S. S. Bhatnagar, professor of physical chemistry, Punjab University; Sir C. V. Raman, director of the Indian Institute of Science, Bangalore; Dr. Birbal Sahni, professor of botany, Lucknow University. The names of three candidates for the scholarship were submitted by the committee to the Commissioners, who decided on June 30 to award the scholarship to Mr. Nath. In addition, it is worth mention that though Indian students, like all other British subjects, have always been eligible for Senior Studentships, if recommended by a university in the United Kingdom, Dr. H. J. Bhabha is the first native of India to be awarded such a studentship. He has made several original contributions to the correspondence columns of NATURE and is well known among workers in theoretical physics.

Rockefeller Travelling Fellowships in Medicine

THE Medical Research Council has awarded Rockefeller fellowships to the following for the academic year 1937-38: D. L. C. Bingham, clinical tutor, Surgical Outpatient Department, Royal Infirmary, Edinburgh; E. G. L. Bywaters, assistant clinical pathologist, Middlesex Hospital, London; P. R. Evans, registrar, Medical Diseases of Children, King's College Hospital, London; J. G. Slater, tutor in clinical medicine, Royal Infirmary, Edinburgh; Dr. E. F. Soowan, assistant director, Medical Professorial Unit, St. Bartholomew's Hospital, London; Dr. C. H. Stuart-Harris, Sir Henry Royce research fellow in influenza, London; G. W. Hayward, ~~resident~~ medical officer, National Hospital for Diseases of the Heart, London. All these fellows propose to work at centres in the United States. In addition, the Rockefeller Foundation has awarded fellowships, on the recommendation of the Medical Research Council, to the following candidates in the

special field of psychiatry, neurology and related subjects: Dr. E. W. Anderson, medical director, Cassel Hospital, Penhurst; Dr. A. Kennedy, assistant medical officer, Maudsley Hospital, London; A. S. Kerr, surgical registrar, Royal Infirmary, Liverpool; Dr. D. J. Williams, resident medical officer, Hospital for Nervous Diseases, Maida Vale, London; Dr. A. F. Rawdon-Smith, senior student, Royal Commissioners for the Exhibition of 1851, working in the Psychological Laboratory, University of Cambridge. Dr. Anderson proposes to work in Germany, the others at centres in the United States.

Announcements

THE following have recently been elected honorary fellows of the Royal Society of Edinburgh: *British*: Dr. W. T. Calman, lately keeper of zoology, British Museum (Natural History); J. L. Baird, inventor of the "Televisor". *Foreign*: Prof. C. U. Ariens Kappers, director of the Central Institute of Brain Research, Amsterdam, and professor of comparative neurology in the University of Amsterdam; Prof. M. T. Bogert, professor of organic chemistry in Columbia University, New York; Prof. Max Planck, emeritus professor of theoretical physics and director of the Institute for Theoretical Physics in the University of Berlin.

DR. G. W. SCOTT BLAIR, of the physics department, Rothamsted Experimental Station, has been appointed head of the chemistry department at the National Institute for Research in Dairying, Shinfield, near Reading. Dr. Scott Blair, who is a chemistry graduate of the University of Oxford, joined the Rothamsted staff in 1926. He has worked on the physico-chemical properties of various agricultural materials such as soil, flour, honey and cheese. During one part of his Rothamsted service he held a Rockefeller Fellowship at Cornell University.

DR. F. W. EDWARDS has been appointed a deputy keeper in the Department of Entomology of the British Museum (Natural History). Dr. Edwards was born in 1888 and entered the Museum service in 1910. He is an authority upon Diptera. He undertook very successful collecting expeditions on behalf of the Museum to Patagonia in 1926-27 and to East Africa in 1934-35, as well as several smaller expeditions.

THE fourth Congress of the Medical Woman's International Association will be held on July 13-18 at the McEwen Hall in Edinburgh. Further information can be obtained from the Local Congress Secretary, 2 Chester Road, Edinburgh.

MESSRS. JAMES TENGASKIS AND SON, 66 Great Russell Street, London, W.C.1, have issued a catalogue of old works on medicine and biology (Caxton Head Bulletin 21). It includes a copy of the rare first edition of Darwin's "Origin of Species", Gesner's "Treasure of Eponymus" (1559), Laennec's "Traité de l'auscultation médiate" (Ed. 4, 1837), the "Opera" (1582) of A. Paré, the great medieval surgeon, and other rare volumes.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 71.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Heat Conduction in Liquid Helium

It was found by Rollin¹ and by Keesom and Keesom² that liquid helium II shows an extraordinarily high heat conductivity, of the order of

the capillary. For example, at 2.10°K ., a level difference of 1 cm. corresponds to a temperature difference of 1.32×10^{-2} deg. Since, on the other hand, the heat flow through the capillary is equal to the heat produced in the wire, one can determine the conductivity.

It is essential for this method that one should actually obtain equilibrium, but it is easily estimated from the observed conductivity that equilibrium should be established in a fraction of a minute, and it was indeed observed that the level followed a change in the current very rapidly and reversibly. It is also easy to see that the heat conduction in the glass, in the leads carrying the current, etc., is negligible. In order to avoid convection, the warm end of the capillary was arranged to be lower than the cold end (the expansion coefficient of helium is negative).

Preliminary experiments showed the un-

Fig. 1.

10^6 cal./deg.cm.sec. We have measured the heat conductivity with the following method, which is essentially a combination of a vapour-pressure thermometer with a liquid-helium manometer. (The method was developed in discussion with Dr. J. D. Cockroft.)

An evacuated glass vessel is immersed in a helium bath. It contains a vertical cylindrical bulb, the bottom of which communicates with the outer bath through a glass capillary. The bulb also contains a heater wire through which a current can be passed. This current is so adjusted that part of the helium in the bulb evaporates, and only part of the bulb is filled with liquid. The level of the liquid is observed in a telescope and its height compared with the level of the bath. In equilibrium, the difference in height is such that the difference in hydrostatic pressure is equal to the difference in vapour pressure. In this way one obtains the temperature difference between the bulb and the bath, and this is practically also the temperature difference between the two ends of

the capillary. For example, at 2.10°K ., a level difference of 1 cm. corresponds to a temperature difference of 1.32×10^{-2} deg. Since, on the other hand, the heat flow through the capillary is equal to the heat produced in the wire, one can determine the conductivity. It is essential for this method that one should actually obtain equilibrium, but it is easily estimated from the observed conductivity that equilibrium should be established in a fraction of a minute, and it was indeed observed that the level followed a change in the current very rapidly and reversibly. It is also easy to see that the heat conduction in the glass, in the leads carrying the current, etc., is negligible. In order to avoid convection, the warm end of the capillary was arranged to be lower than the cold end (the expansion coefficient of helium is negative). Preliminary experiments showed the un-

expected result that the conductivity depends on the temperature gradient. We therefore used an arrangement in which the level difference could vary from 12 cm. to about 0.3 mm., and measured the heat flow as a function of the temperature difference ΔT between the ends of the capillary. In this case the capillary was 16.8 cm. long and had an internal diameter of 1.45 mm. The results are shown in Fig. 1, for bath temperatures of 2.06° and 1.34°K . It is clear that the heat flow is far from being proportional to ΔT , even for the lowest temperature differences we used. The ratio of heat flow to temperature gradient, which one may call conductivity, increases with decreasing ΔT . It reaches the value 1.1×10^6 cal./deg.cm.sec. at $\Delta T = 5 \times 10^{-3}$ and $T = 2.06$. It appears, however, to rise still further and a refinement of the method is required to decide whether it tends to a finite value as ΔT tends to 0.

Qualitative measurements at a number of different temperatures between 1.34° and 2.19° showed the same general behaviour. At constant ΔT , the

conductivity is relatively small near the λ -point (2.19°), reaches a maximum in the neighbourhood of 2.0° and decreases again at lower temperatures.

We cannot suggest an explanation for these results, for which there is no analogy in the behaviour of other substances. It seems impossible, however, to account for them by any errors in the experimental method; the effect seems actually to be a property of the liquid helium II.

Analysis of Ternary Gas Mixtures by Thermal Conductivity Measurements

It frequently happens in the course of exchange reactions with deuterium and hydrogen that a third gas is present initially, or is produced during such experiments (for example, nitrogen in exchange reactions with ammonia and deuterium). If this gas is non-condensable in liquid air, the deuterium content of the gas cannot be estimated by the convenient thermal conductivity methods, unless a trap cooled with liquid hydrogen is employed to freeze out the third constituent of the mixture. The gases concerned are oxygen, nitrogen, carbon monoxide and methane and the inert gases. The only alternative method is to burn the gases and measure the deuterium content of the water so produced.

The thermal conductivity method described below surmounts this difficulty. Its operation depends on the fact that the thermal conductivity of hydrogen decreases rapidly below 200° K., owing to the decrease in rotational specific heat of the molecule. The thermal conductivity of deuterium, on the other hand, only decreases slowly, since the rotational specific heat remains practically constant down to

Fig. 1.

about 80° K. For example, at 250° K. the ratio of the thermal conductivities is 1.584 : 1; at 75° K. it is 1.095 : 1. Consider now a ternary mixture containing hydrogen, deuterium and a third gas (X). At high temperatures (c. 250° K.) a whole series of mixtures will have the same thermal conductivity—as is exemplified by the full lines on the ternary

diagram (Fig. 1). At 75° K., however, the isothermal conductivity lines will be more nearly parallel to the hydrogen-deuterium side of the triangle, as is indicated by the dotted lines. To perform an analysis of an unknown mixture, then, it is only necessary to measure the thermal conductivity at these two temperatures: if, for example, the respective thermal conductivities correspond to the lines *aa* and *bb*, the point of intersection at once gives the composition of the mixture.

Fig. 2.

In practice, the analysis may be carried out by compressing the mixture to a standard pressure, for example, 50 mm., into a micro thermal conductivity cell, of volume 0.05 c.c. (that is, requiring about 0.01 c.c. gas at N.T.P.), dipping into liquid air and attached to the compression capillary of a McLeod gauge¹. The voltages required to maintain the filament at the two chosen temperatures are determined. The isovolt lines obtained for hydrogen-deuterium-nitrogen mixtures are shown in Fig. 2. The filament temperature was 300° K. and 110° K. in the case of the full and dotted lines respectively. The observed voltage value, relative to that required for pure hydrogen, corresponding to each isovolt line is indicated. The observed curvature of the high-temperature lines is attributable to mixture effects. For mixtures of nitrogen-content not exceeding 50 per cent, the accuracy of the method is about 1 per cent deuterium.

It is evident that this method may be applied to any ternary mixture, one component of which is hydrogen and the other two, gases of different thermal conductivity. Mixtures of ortho- and para-hydrogen and a third gas may likewise be analysed.

Artificial Slip Formation in Crystals.

WHAT is the cause of the plasticity and low elastic limit of crystals? No satisfactory answer has as yet been found to this fundamental question in crystal

All the photographs show the artificially created slips in polarized light. The axes of the Nicols are parallel to the cube axes. The scratches are made in the direction (100) normally to the plane of the

Fig. 1.

Fig. 2.

physics. The results of experiments, briefly described in the present note, establish one of the factors determining the course of the plastic deformation.

A scratch was made on a rectangular specimen of rock salt with faces parallel to the cube faces. The scratched crystal was placed between crossed Nicols and stretched. The influence of the scratch on the process of slip formation was observed with polarized light.

The main result may be summarized in the statement that a scratch is the source of the slip.

The gradual propagation of the slips beyond the region of the scratch, and their growth throughout the bulk of the crystal, were observed directly. The bright rays in Fig. 1, Fig. 2 *a* are artificially produced slips. They were especially pronounced when the scratches were made on specimens the original surfaces of which had been previously dissolved away.

The picture formed by the artificially produced 'slips' depends upon the experimental conditions. With different positions of the scratches on the surface of the crystal, we could obtain any desired slip patterns. Fig. 2 *b* corresponds to three parallel scratches at a distance of 5 mm. from each other. Fig. 2 *c* corresponds to 10 parallel scratches at a distance of 0.5 mm. from each other.

A number of details in the photographs may be noted, such as (1) the increased illumination in the parts lying along the locus of the intersection of the slips, with a straight line drawn at an angle of 45° to the axis of the specimen from the scratch (see Fig. 1, dotted in the upper ray); (2) the direction of the slips deviates considerably from 45° (see Fig. 2 *a*); (3) the interference of several scratches (see Fig. 2 *c*), etc. Fig. 3 shows a part of one of the rays reproduced in Fig. 1 at a greater magnification.

It appears that the plastic deformation of crystals cannot be explained by a simple slipping mechanism. The rupture takes place along the scratch. The process of rupture proceeds as follows: the surface defect gives rise to the appearance of slips, which in their turn lead to the development of a surface defect, which ends in fracture.

The state of the surface and local deformation are probably also of importance in twinning.

picture. The arrows indicate their position. The scratches were produced by means of a Martens sclerometer.

Fig. 3.

A detailed account of these experiments will shortly be published in the *Phys. Zeitschrift der Sowjetunion*.

Coupling of Dismutations with Esterification of Phosphate in Muscle

THE disappearance of free phosphate during glycogenolysis in muscle extract is a striking phenomenon. One mechanism by which this occurs has recently been elucidated by Parnas and his colleagues¹, who showed that, even in long-dialysed extracts, phosphate and glycogen can react together giving hexosemonophosphate. This reaction is poisoned by *M*/100 phloridzin, but not by *M*/400 iodoacetic acid. We have observed a second method of phosphate esterification.

A certain dependence of esterification of carbohydrate upon dismutation has from time to time been observed, for example, by Meyerhof and Kiesel² in yeast and muscle extract, by Schaffer and Berl³ in yeast extract, and by Dische⁴ in red blood cells and haemolysed blood. Dische mentions having found an increase in easily hydrolysable phosphate during this esterification, and suggested that the synthesis of adenylypyrophosphate might be an intermediate step. We now show that in the second method of phosphate esterification in muscle extract

the dismutation of triosephosphate with pyruvic acid (giving phosphoglyceric and lactic acids) is coupled with a synthesis of adenylypyrophosphate from adenylic acid and free phosphate.

As enzyme preparation we used extract of acetone muscle powder (rabbit) prepared according to Meyerhof's technique. In order to destroy adenylypyrophosphatase (the activity of which would have masked any adenylypyrophosphate synthesis) we kept the extract at 0° for five days before use; the extracts were also dialysed for four hours to remove any remaining traces of substrate. Typical results are given in Table 1. It will be observed that (1) iodoacetate, which inhibits the dismutation, inhibits also the esterification, (2) phloridzin does not inhibit either dismutation or esterification, (3) arsenate inhibits the esterification without affecting dismutation.

TABLE 1.

1 c.c. extract made up to final volume of 2.5 c.c. with *M*/100 hexosediphosphate, *M*/50 pyruvate, *M*/50 fluoride, *M*/50 phosphate, *M*/200 adenylic acid, present in each sample. 0.4 mgm. co-enzyme present in each. 30 min. incubation at 37° C. The figures give increases and decreases in mgm.

Exp.		Lactic acid	Phosphoglyceric P	Inorg. P.	Pyro P.
IV		+ 1.58	+ 0.57	- 0.62	+ 0.66
V	No iodoacetate	+ 1.80		- 0.73	+ 0.73
	+ iodoacetate	+ 0.32		0	0
XVIII	No phloridzin	+ 4.56		- 0.51	+ 0.57
	+ phloridzin	+ 3.87		- 0.45	+ 0.66
XIX	No arsenate	+ 4.26		- 0.60	
	+ arsenate	+ 4.06		- 0.18	

Iodoacetate *M*/400; phloridzin *M*/100; arsenate *M*/75.

The dismutation of α -glycerophosphate with pyruvate, and the dismutation of hexosediphosphate to give glycerolphosphate and phosphoglycerate can be coupled with the phosphorylation of adenylic acid.

As regards the mechanism of the coupling, it can be said (1) that we have tested our extracts for adenylypyrophosphatase activity and found it to be nil. It seems, therefore, that the coupled esterification cannot be dependent upon a reversed reaction catalysed by this enzyme. (2) We have examined the ratio of lactic acid formed to phosphorus esterified. The results indicate that, according to the conditions, a greater or less proportion of the dismutation can be coupled with adenylypyrophosphate synthesis, but that however favourable the conditions, probably not more than one atom of phosphorus can be esterified per molecule of lactic acid formed.

This coupled esterification of phosphate probably plays an important part during the anaerobic recovery period when creatinephosphate is resynthesized, free creatine and free phosphate disappearing. Making use only of the Parnas mechanism of esterification of glycogen by free phosphate, and of the mechanism whereby phosphate is transferred from phosphopyruvic acid to adenylic acid, it seems possible to account for the resynthesis of only $\frac{1}{2}$ mol. creatinephosphate per mol. lactic acid produced. Both Meyerhof² and Parnas³ have pointed out that Lundsgaard⁴ has actually observed a much greater synthesis than this—2 mol. creatinephosphate per mol. lactic acid formed. By taking into account the coupled esterification, synthesis of $1\frac{1}{2}$ mol. of creatinephosphate per mol. lactic acid can be expected. This is a value much nearer Lundsgaard's observed results. Further, during anaerobic recovery there is very little heat output; this can only be explained if the energy of dismutation is not evolved. We here

suggest that it is retained and used to make possible the endothermic synthesis of adenylypyrophosphate.

These considerations will be dealt with in detail elsewhere.

An Oxyporphyrin Haematin Compound as Intermediate between Protohaematin and Verdohaematin

In our letter on "Coupled oxidation of ascorbic acid and haemochromogens"¹, we had observed the formation of a haematin compound with an absorption band at 639 m μ during the coupled oxidation of pyridine-haemochromogen and ascorbic acid. The same compound was formed by action of hydrogen peroxide on the haemochromogen in presence of ascorbic acid. On reduction it gave a haemochromogen with the bands of protohaemochromogen. From these observations we had concluded that the compound was a hydrogen peroxide compound of protohaemochromogen.

We have now found that the haemochromogen, obtained by reduction of the compound with the absorption band at 639 m μ , is not protohaemochromogen, but a haemochromogen of a new type. The position of its absorption bands is almost the same as the position of the protohaemochromogen bands (557.4 and 526.3 m μ), but the second band is stronger than the first, whereas in protohaemogen the first band is the stronger of the two. A haemochromogen of a similar type is that of phylloporphyrin², a porphyrin carrying methyl on one methene group. By atmospheric oxygen the new haemochromogen is rapidly oxidized to verdohaemochromogen, a haemochromogen with open tetrapyrrolic chain. On splitting with hydrochloric acid in absence of oxygen, the new haemochromogen gives rise to an oxyporphyrin, which resembles the oxyporphyrins obtained by H. Fischer and collaborators by action of hydrogen peroxide on porphyrins in concentrated sulphuric acid³. The absorption spectra of the oxyporphyrins of Fischer and also of our oxyporphyrin are similar⁴ to those of chlorins and rhodins, but whereas the copper and iron complex salts of Fischer's oxyporphyrins are also chlorin-like, the complex salts of our oxyporphyrin are of the phylloporphyrin type.

The most likely explanation appears to be that our haemochromogen is the iron complex salt of an oxyporphyrin carrying a hydroxyl group on the α -methene group. By action of molecular oxygen on the oxyporphyrin-haematin, this carbon atom is then removed and the porphyrin ring opened. Fischer's oxyporphyrins carry their hydroxyls probably not on the methene group, but in the β -positions of a hydrogenated pyrrole nucleus⁵. The compound with the absorption band at 639 m μ is the ferric haemochromogen of the oxyporphyrin, and not a haem-hydrogen peroxide compound.

The conclusions, drawn from the existence of the supposed hydrogen peroxide compound with regard to the reaction mechanism of the coupled oxidation of haemochromogen and ascorbic acid, remain, however, correct. Hydrogen peroxide plays a part in this reaction, transforming porphyrin-haematin into oxyporphyrin-haematin. There is also evidence in favour of the existence of a haem-hydrogen peroxide compound during the reaction. Whereas catalase completely prevents the formation of the oxyporphyrin-haematin from haemochromogen and hydrogen peroxide, catalase inhibits the formation of this compound (and of verdohaemochromogen) by atmospheric oxygen only partially. The most likely explanation is that the 'nascent hydrogen peroxide' is protected from the action of catalase by its combination with the molecule with which it is to react afterwards (that is, the haem), and that the partial inhibition of the reaction by catalase is due to a partial dissociation of the haem-hydrogen peroxide compound and catalytic destruction of the hydrogen peroxide set free by the dissociation.

Mechanism of the Glass Electrode

It is a well-known fact that new glass electrodes are not suitable for exact measurements until they have first been allowed to stand in water for some time. The continuous variation in potential observed with a new electrode may be connected with the property of the glass of taking up hydrogen ions. I have demonstrated¹ that hydrogen ions are exchanged for calcium and sodium ions in the glass electrode. The following experiments demonstrate the relation of the potential to the hydrogen ion uptake.

A series of bottles containing 2 gm. each of glass powder and 30 ml. of 0.1 *N* HCl were shaken at 25°. At different times bottles were removed and the liquid titrated with 0.1 *N* NaOH. From these data the amount of 0.1 *N* HCl (*C*₁) disappearing, equivalent to the amount of H taken up by the powder, after various lengths of time were found. The results of the titrations are given in Curve A (Fig. 1).

In order to determine whether measured potentials agree with those calculated from consideration of the chemical changes which occur, the following experiment was performed.

A spherical glass electrode was placed in each arm of a U-tube containing 30 ml. 0.1 *N* HCl and 2 mgm. glass powder in order to approximate the conditions in the experiment previously described. The inside of both electrodes and the outside of one of them had been in contact with 0.1 *N* HCl for a month, but the remaining outer surface had never been in contact with any solution. Silver wires covered with silver chloride were placed in contact with the inner liquid of both electrodes. The potentials of this system were measured periodically and the data obtained are represented by Curve B (Fig. 1).

In order to correlate the hydrogen ion uptake and the above-mentioned change in potential of new electrodes, the following assumptions have been

made. The initial hydrogen ion activity of the glass is assumed to be Pc_0 , where P is a constant, and c_0 is the number of hydrogen ions in the untreated glass per arbitrarily chosen unit of glass surface. At any time, t , after the immersion of the new electrode in hydrochloric acid, the number of hydrogen ions taken up is α , and the activity is now assumed to be equal

Fig. 1.

to $P(c_0 + \alpha)$. Hence the variation of potential with time of the system is, when π is measured in millivolts, given by the equation:

$$\frac{d\pi}{dt} = \frac{RT}{F} \cdot 1,000 \frac{1}{c_0 + \alpha} \frac{d\alpha}{dt}$$

The values of $d\pi/dt$ and $d\alpha/dt$ at definite times are found graphically from Curves A and B in Fig. 1. The value 2.51 was found to be an approximation for c_0 . The details of the method of determining this value will be published elsewhere. This value means that 2 gm. of glass powder at the start of the experiment has a H ion content equivalent to 2.51 ml. 0.1 *N* HCl.

In Fig. 1, Curve C was constructed from the data obtained in the glass powder experiment and the points represent the values of $d\pi/dt$ derived from potential measurements.

From these experiments it appears that the suitability of a glass as an electrode depends upon its ability to exchange sodium and calcium ions for hydrogen ions. These experiments also confirm the hypothesis of Horowitz² published in 1923. From this point of view it should be possible to produce sodium, calcium and potassium electrodes by choosing a glass of the proper composition or a mineral of the permutit type. I am carrying out further investigations of these possibilities.

Controlled Cathode Sputtering

THE object of these experiments is to obtain accurate measurements relating to the phenomenon of cathode disintegration in gaseous discharges.

The apparatus consists essentially of a strong ion-source of the Lamar-Sameon-Compton type¹, capable of delivering 2 milliamperes of singly-charged argon ions, and of an adjacent 'sputtering chamber' maintained at about 2×10^{-4} mm. mercury pressure, where the material to be tested is sputtered and measurements relating to that process are made.

The first objective is to obtain measurements of the amount of material sputtered per unit time as a function of the ion-current density and ion-energy. As shown in the diagram (Fig. 1), the ions emerging

Fig. 1.

from the source (which is earthed) are allowed to impinge on and sputter a target maintained at a negative potential. Some of the material sputtered is deposited on a mica collector placed in front of the target, and supported by a horizontal fine quartz fibre. The weight of the deposit collected (a few milligrams) can readily be determined by observing the deflection of the fibre by means of a microscope. This allows measurement of the relative rates of sputtering. The total amount of material sputtered can be computed in cases where the law of angular distribution of sputtered deposit over a sphere is known².

The rate of sputtering of gold by argon ions of 6,000 volt energy has been determined. The sputtering rate is sufficient to deposit measurable amounts in $3\frac{1}{2}$ hours. With decreasing ion energy the rate of deposition decreases, and for ions of 2,000 volt energy, about 10 hours would be required to deposit a measurable amount. This is the maximum period over which the apparatus has been operated steadily. Because of the complicated nature of the apparatus, it seems impracticable to extend the time of the test. Therefore to obtain the rates of sputtering at lower voltages a construction of the sputtering chamber has been achieved, which still allows weight determinations, and in addition permits light transmissivity measurements of sputtered deposits.

The determination of the rate of sputtering of a given substance is complicated in some instances by a copious secondary electron emission from the bombarded target. Thus the apparatus is used at present in a somewhat modified arrangement for study of

this secondary electron emission from solid metals bombarded by argon ions.

X-Ray Intensifying Screens adapted to Structure Analysis

THE intensifying screens in use for medical radiography cannot be employed to reduce times of exposure when working on tissue fibres, as they are not sensitive to the radiation used in structure analysis. However, Messrs. Ilford, Ltd., London, have now produced a screen, the Ilford Fluoraxure intensifying screen (Levy-West), which proves to be very suitable for this purpose; this screen was put at our disposal by Mr. Chr. J. Bruno Wittgreffe, of the X-Ray Section, Ilford Co., to whom our best thanks are due for this kindness.

Fig. 1.

X-RAY PHOTOGRAPH OF A COPPER WIRE, TAKEN AT 40 kV. (a) ILFORD FILM WITHOUT SCREEN; EXPOSURE 45 MIN. (b) ILFORD FILM WITH A FLUORAXURE SCREEN AT THE BACK; EXPOSURE 15 MIN.

While we expected that increase of line width would counteract the advantages from eventual intensifying to such an extent that the photographs obtained would only be suitable for approximate work and not for exact measurements, we were quite astonished to find not only actual intensifying (3 times at 40 kV.) but moreover practically no increase of width, which seems a very important feature in the new screen. As appears from the photographs reproduced herewith (Fig. 1), it has proved possible to obtain films suitable for exact measurements. The photographs were taken with a Philips Metalix tube with copper-anticathode and a nickel filter of 0.01 mm. The Debye-Scherrer camera had a radius of 2.77 cm., while the diaphragm consisted of two pinholes 0.5 mm. diameter, separated by 6 cm. A copper wire of 0.6 mm. diameter was taken as a sample. Unless otherwise stated, the photographs were taken at 40 kV. and 15.5 mamp.

First a photograph was taken on an Agfa-Laue film, the usual material for structure analysis. Proper blackening was obtained after 75 min. exposure. Then the experiment was repeated using an Ilford film. To get the same blackening as in the former case, an exposure of 45 min. proved to be necessary. The grain of the Ilford film is slightly coarser, but still within admissible limits (see Fig. 1, a). Thirdly,

we made a photograph on an Ilford film on the back of which a Fluorazure screen (Levy-West) was placed (Fig. 1, b). Identical results were now obtained with exposure reduced to 15 min., while there appeared to be practically no increase of width.

While at the ends of Fig. 1, a, the subdivision into α_1 and α_2 lines is fairly visible, Fig. 1, b still gives some slight evidence of their presence.

Other experiments were made at 30 kV. with an Ilford film at the back of which was a Fluorazure screen; the exposure was 15 min. While giving better contrast, blackening proves to be less; so that here the disadvantage seems to outweigh the advantage.

As usual in medical radiology, we also placed screens in front of and at the back of the film, but this gave, as might be expected, less blackening in the same time than with a screen at the back only; moreover, increase of width becomes manifest in that case.

We suggest that the use of Fluorazure screens is helpful in structure analysis; especially with the long exposure necessary in fibre research, it has evident advantages. Meanwhile, further research is being conducted along these lines.

Living Animal Cases of Congenital Porphyrinuria

SOME time ago, in a single herd of grade short-horn cattle, running with one bull, on a farm in Swaziland, five living cases of congenital porphyrinuria were discovered. From the account given by the farmer, there had been seven other cases in the herd. Only one bull (a pure-bred, roan shorthorn)

Fig. 1.

PHOTOSENSITIZATION LESIONS ON BACK OF 'ORDARA',
A COW SUFFERING FROM CONGENITAL PORPHYRINURIA.

had been used during this period, and on an adjoining farm where he had also been employed, one case had occurred with certainty. The bull himself is normal but his dam was said to have been an unthrifty animal; possibly she, also, may have been a porphyrinuric.

The bull, four of the affected cattle and others, most of which are descended from him but normal, have been acquired by this Laboratory with a view to intensive study of the clinical features of the disease and its mode of inheritance. The fifth affected animal was slaughtered and a detailed chemical investigation carried out *post mortem*. In the forthcoming number of the *Onderstepoort Journal of Veterinary Science* (7, No. 2) papers are contributed by the writers of this note describing in full their findings. The two most severely affected animals each excrete about 0.6 gm. coproporphyrin and 0.06-0.07 gm. uroporphyrin daily, the others about half these quantities only. They show signs of photosensitization.

We also wish to record that a female calf which suffers from the disease has now been born at the Laboratory. It was the progeny of the bull with one of his normal daughters. The animal was seen approximately two hours after its birth, and the teeth were then distinctly pinkish-brown in colour. It is red-coated and although small is not apparently seriously handicapped in any way. It passes about 7.7 mgm. coproporphyrin per 100 gm. dry weight of faeces and about 40 γ per 100 ml. in the urine. A second heifer calf, born on the same day, sired by the bull out of another normal daughter, is perfectly normal in every respect. It excretes 0.41 γ coproporphyrin per 100 ml. of urine and but traces, only recognizable fluoriscopically, in the faeces.

Yet another case has recently been discovered, quite unrelated to the herd described above. This is a black-and-white cow about eight years of age. She shows marked lesions of photosensitization, involving only the white areas of skin on the back (see Fig. 1). This cow is in calf to a normal bull. She has reared one calf previously (apparently normal) but has also aborted.

A histopathological study of the bones and organs taken from the porphyrinuric animal which was killed is being made with the aid of an ultra-violet fluorescence microscope, and these findings will be published shortly. The bones, it may be mentioned, show on cross-section annular zones of pigment of varying intensity.

We believe these to be the first living cases of porphyrinuria in animals ever to be described, and the wealth of our material makes it highly probable that by breeding experiments we may be able successfully to elucidate the mechanism of inheritance of this very rare metabolic anomaly.

Sex-Biology of the Oyster and the Salmon

THERE are similarities in the sex-biology of the oyster, *O. edulis*, and the salmon, *Salmo salar*, which may prove to be fundamental in character.

It is known that very young salmon remain in fresh-water as parr a variable time. Very rapid growth in the first year of life is often followed by development of the sea-migratory instinct, when the young fish acquires the attributes of, and departs for the sea as, a smolt. On the other hand, slow-growing parr may remain in fresh-water two, three or four years¹.

Just as certain smolts become sexually mature after one year in the sea and return as grilse to fresh-water to spawn, so in certain warm seasons in England, and more frequently in warmer and more southerly latitudes, do oysters mature as females at an age of one year¹. Other individuals of *Salmo salar* and others of *O. edulis* do not mature sexually until they are older, or rather other *O. edulis* certainly do not mature as females until they are older. In the case of this oyster there can be little doubt that environmental conditions govern the first onset of female sexual maturity, and it is considered a reasonable hypothesis to assume that the same conditions are operating on salmon.

In the oyster, all the factors operating in the attainment of sexual maturity at an age of one year are not known, but relatively high temperature (accompanied doubtless by a correlated type of metabolism), rapid feeding and rapid growth are known factors. But rapid feeding and growth result in the sea-migratory impulse in parr, and there are indications that the same factors may be operating in inducing sexual maturity in certain salmon after one year in the sea. It is known, however, that grilse are largely those fish which have had a long life as parr, and it is at this point where 'excess metabolism' or 'physiological reptition' does not quite account for the assumption of the sexual phase, as there appear to be good grounds for the deduction that younger fish may grow at a greater rate than grilse and yet not return to fresh-water to spawn. At least two primary factors are therefore involved: (1) relative adolescence and (2) rate—and perhaps nature—of metabolism.

The attainment of the adult organization in free-living animals may be presumed to be generally essential for the assumption of a preparation for female sexual maturity. In the oyster, again, it is stated that sexual maturity in a female may be delayed in colder localities until the animal is three years old², although the oysters at this age may be far bigger than the one-year-old females found in the warmer hydrographical localities.

It would seem that in these considerations may be found a solution of the problem of the varying ages of sexual maturity in the salmon and the oyster. Among invertebrates, growth in spring may be relatively great before larvae are produced and a much larger size attained than in the summer broods³, hence the temperature and rate at which good feeding occurs in these forms is more important for breeding than the amount of food consumed, and good growth may take place without the production of genital products. The oyster appears to conform to the same principle, but whether the same holds for the salmon must await further information. There is, however, nothing at variance with known biological phenomena in the possibility of homogenetic eggs from one salmon giving rise to smolts of different ages and also to either grilse or first spawning salmon of different ages.

The interesting facts regarding the high proportion of males among grilse, the change in proportion of grilse and salmon and the decline of grilse taken generally, are explicable on the varying opportunities smolt may have of feeding under different conditions in the sea. Loss of feeding grounds, for example, would entail a longer sojourn in the sea to build up the body requirements, so that the decline of hake, for example, might be correlated with the reduction in the proportion of grilse now taken; and in general,

unknown fluctuations of salmon food in the sea may be related to fluctuations in the sea-life of smolts.

Fundamental researches on the biology of insignificant invertebrates may therefore reveal principles applicable to important food fishes such as salmon and—by a modification of the argument given above—also to herring.

Nocturnal Habits of *Platyedra gossypiella* Saunders

In the course of investigational work on *Platyedra gossypiella*, the pink bollworm of cotton, in the West Indies, observations were made on its nocturnal habits, concerning which but little is known. On the question of light attraction, for example, there has been a stalemate of opinions. Wilcocks¹ in Egypt found that both sexes came to light readily; while Busck² in Hawaii states that the moth is not attracted to light "but is on the contrary shy of all light, natural and artificial". "The idea", he writes, "that moths were attracted to light is based on very un-

Fig. 1

satisfactory evidence and is probably due to a misidentification of material collected in the traps³. In St. Vincent, B.W.I., light attraction is evident from 8 p.m. to 4 a.m., when it falls rapidly. By 5 a.m., though it is still dark, the moths are hiding as by day. In Egypt, Ballou⁴ found that there were always some moths that were not attracted. This difference has also been observed in St. Vincent and is not due to age, sex or condition. Attraction is strongest during the mating period. Wedded pairs are readily attracted, but in all cases prolonged exposure tires the response. There is no noticeable difference between the behaviour of long- and short-cycle moths.

Copulating moths take up the end-to-end position. Mating is curiously restricted to the last two hours of the active period (Fig. 1). The couples are docile

and do not readily separate. Copulation takes place soon after emergence (Fig. 2), lasts for 1-2 hours, and is not repeated.

Fig. 2

The moths feed at all hours of the active period on sugar solution, fruit or on the secretion of the nectaries at the base of the cotton bolls. Oviposition, which usually commences on the third day after copulation, likewise takes place at any time of the night.

A Double Refraction Effect in Certain Fatty Materials

THE projection refractometer is particularly suitable for the examination of some doubly refracting materials, the properties of which do not appear to be widely known.

Certain fatty materials the refractive indexes of which are known have, in fact, two refractive indexes. On the ordinary refractometer in which the light is transmitted through the material to be tested, the border line of total reflection due to the higher index is not usually seen, since there is much greater contrast at the border line due to the lower index. The space between the two border lines is plane polarized, the vibrations taking place in a direction parallel to the border lines. Thus, these materials appear to behave as though they were doubly refracting.

It has been known for some years that soap gives these two border lines under certain conditions. Recently some other materials were investigated, and it was found that

vaseline, lanoline; rubber lubricant, ordinary yellow soap, and the pure green soft soap, all give the two border lines referred to. On the other hand, various thick lubricants give only one border line.

It was found that vaseline, lanoline and the rubber lubricant, if melted and dripped on to the refractometer prism, give only one border line, that due to the lower index; but if the material is then smeared while it is still upon the prism, thus removing any possibility of micro-crystals being orientated in a particular direction, the second border line appears, and in the case of lanoline treated in this way, there is a trace of a third border line. In the case of moistened yellow soap, the difference in refractive index is about 50 per cent greater than the difference between the ordinary and extraordinary rays of quartz.

The projection refractometer has a single horizontal prism surface upon which material is placed. Light from an internal source is totally reflected at the interface of the prism and the material being tested. None of the materials mentioned above gives a sufficiently sharp border line to allow of readings closer than the third decimal place.

Collision of Two Oil Drops and the Stability of a Non-spherical Oil Drop

It has been found that the oil drops used in our investigation on the determination of the electronic charge show large variations in the time of descent, t_p , and ascent, t_r , with time, and consequently the greatest common divisor e_1 . This is true of all oils experimented with, such as Apison A and B, Nye's superfine clock oil and others, except our newly prepared animal oil (which shows little or no change). Nevertheless, it makes necessary the careful study of the time variations of these three quantities. The results may be stated as follows:

There are four distinct classes of drops.

(1) 50 per cent of the total number are spherical drops which behave normally.

(2) With a few drops, collision of two unequal spheres forms a pear shape drop, showing very large

Fig. 1.

discontinuities in the curves. The resulting drop becomes a sphere within a short time.

(3) For 20 per cent of the drops t_f and t_{f-s} increase for the first five minutes at the same percentage rate. These drops are found to be oblate spheroids with eccentricity gradually decreasing with time, and becoming spheres.

(4) For 30 per cent of the drops, as shown in Fig. 1, while the time variation curve of t_f is very regular, that of the greatest common divisor τ_1

shows discontinuities which depend upon the number of charges on the drop, and the greater the number the smaller the common divisor. This class of drop is stable for hours. They are presumably prolate spheroids.

Points from Foregoing Letters

THE heat conductivity of liquid helium II at 1.34° and 2.06° K. has been measured by Dr. J. F. Allen, Dr. R. Peierls and M. Zaki Uddin, by means of a new method consisting essentially of a combination of a vapour-pressure thermometer with a liquid-helium manometer. The results show that the heat conductivity of liquid helium II depends upon the temperature gradient, an unusual behaviour for which, the authors state, they can offer no explanation.

A convenient method of analysing ternary gas mixtures, containing hydrogen as one component, by means of thermal conductivity measurements, is described by J. L. Bolland and Dr. H. W. Melville. The volume of gas required may be reduced to 0.01 c.c. at N.T.P., by using a suitable micro-conductivity cell.

Photographs showing slip-formation in crystals of salt the surfaces of which have been scratched and then stretched, are submitted by A. W. Stepanow. The photographs, taken in polarized light, show that the surface scratches give rise to slips; these in turn increase the surface defect, which ends in fracture.

From the effect of iodoacetate, phloridzin and arsenate upon the lactic acid formation in muscle extract, Dr. Dorothy M. Needham and R. K. Pillai deduce that the oxidation-reduction of triosephosphate with pyruvic acid is coupled with a synthesis of adenylypyrophosphate from adenylic acid and free phosphate. They suggest that this coupled esterification of phosphate may play an important part during the anaerobic recovery period in the muscle, when there is little heat output. The energy developed by the first reaction, they consider, may be taken up by the second.

A substance with absorption band at 639 m μ , which Dr. R. Lemberg, B. Cortis-Jones and M. Norrie recently deemed to be a hydrogen-peroxide compound of proto-haemochromogen, appears, according to further tests by the same authors, to be the ferric haemochromogen of an oxyporphyrin carrying a hydroxyl group on the α -methene group.

A graph showing the amount of hydrochloric acid taken up by powdered glass after given periods of time, and another giving the change in electric potential of a new glass electrode with time, are submitted by G. Haugaard. From these, the author infers that the suitability of a glass as an electrode depends upon its ability to exchange sodium and calcium ions for hydrogen ions, and that it should be possible to produce sodium and calcium electrodes by choosing a glass of proper composition or a mineral of the permutit type.

An apparatus has been built at the Massachusetts Institute of Technology by Dr. Gregory Timoshenko for studying controlled sputtering of metals under the impact of positive ions. The apparatus in its present form allows accurate measurements of the rates of sputtering and of secondary electron emission from various solid metals bombarded by argon ions having an energy of 8,000–2,000 volts.

Photographs are submitted by Dr. N. H. Kolkmeijer, C. J. Krom and H. Kunst to show the usefulness of the Ilford 'Fluorasure' screen in shortening the exposure time needed to obtain X-ray photographic patterns of fibres for the analysis of their structure.

Several cases of animals suffering from congenital porphyrinuria, a rare disease in which porphyrin (a red decomposition product of haematin, but containing no iron) is excreted, are described by P. J. Fourie and Dr. Claude Rimington. Some of the animals are living, and the authors hope, by means of breeding experiments, to elucidate the mechanism of this peculiar metabolic anomaly, which also renders the skin of the animals sensitive to light.

Prof. J. H. Orton finds that, in the oyster, environmental conditions (that is, higher temperature, rapid feeding and rapid growth) influence the first onset of female sexual maturity. He points out that similar conditions result in the sea-migratory impulse in parr (young salmon in fresh-water). The sexual maturity in salmon, which induces them to return from the sea to fresh-water, appears to depend both upon age and size, which is a factor of environment. This may explain the varying ages of sexual maturity in the salmon and the oyster.

The nocturnal mating habits of the pink bollworm of cotton (*Platyedra gossypiella*) are described by F. A. Squire. The author points out that the moths are attracted by light only during certain hours of the night, which may account for the divergence of opinion expressed on the subject by different observers.

L. Bellingham finds that vaseline, lanoline, rubber lubricant, and certain soaps, have two refractive indexes when tested by the projection refractometer. If melted and dripped on the refractometer prism, the lower index is observed, but if smeared upon the prism so as to prevent orientation, the higher index becomes effective.

During experiments on the fall of electrified oil drops (for the determination of the electronic charge), Y. Ishida has identified four types of drops, according to their shape and the variation in the time of their fall.

Research Items

Prehistoric Archaeology of North-Eastern New Mexico

PROF. E. B. RENAUD, in his ninth report on the archaeological survey of the High Western Plains, which he is carrying out on behalf of the University of Denver, deals with the north-eastern area of New Mexico, which has been visited in summer field-work on various occasions since 1930. For archaeological purposes, the region has been divided into six districts covering the three areas of drainage—the Dry Cimmaron, the Canadian River, and the Pecos River. The region as a whole contains a large number of archaeological sites, of which 211 have been reported. Of these, the most common is the camp site, but other indications of the presence of man are tipi rings, grinding stones, potsherds and factory sites. No less than 86 camp sites have been recorded. 'Scattered finds' number 67. An important but difficult source of material is the 'blow-out'—hollows in sandy soils and dunes caused by various agencies, natural and other, at the bottom of which archaeological and sometimes paleontological material has collected. The region is of archaeological importance as the peripheral area of two cultures, the Plains culture and the Pueblo. This is reflected in the pottery, which has been examined, classified and discussed in detail. The distinctive character of the two types and their subdivisions are clearly shown. The lithic industry, however, in this area is of more importance than the ceramic. Two successive cultural phases are distinguished—the Basket-makers and the Pueblo. Of the former, the earliest phase is the 'Fumarole' culture, first discovered by Prof. Renaud and Mr. H. J. Cook. The 'fumaroles' or mounds then examined were found to cover rock shelters. The stone implements from the 'fumaroles' fall into three classes. Of these, the largest and most important, constituting the true 'fumarole' industry, is of quartzite, flaked by percussion and Mousterian in appearance. This 'Fumarole' culture is clearly anterior to the Basket-makers of the caves of Oklahoma and New Mexico, and may represent the nomads who are postulated as preceding the true Basket-makers.

Longevity of Monkeys

Two aged macaques are described by Prof. W. C. Osman Hill, both of which lived in Ceylon (*Spolia Zeylanica*, 20, Pt. 2, 255; 1937). One, a male toque macaque, *Macaca sinica*, was an experimental specimen of the Government Bacteriological Institute, Colombo, and had been used by Sir Aldo Castellani in his experiments on yaws which were published in 1907. It died on March 2, 1936, when it was known to be at least thirty years of age, and was probably thirty-five. Thus it exceeded the recorded age of any of its congeners, although the macaques are outstanding amongst monkeys on account of their length of life. The second specimen, a male Celebesian black macaque, *Macaca nigra*, was full-grown when purchased for the Trivandrum Zoo on June 15, 1907. It died in 1933 after twenty-six years of captivity, and must have been several years older. Flower states that the black ape seldom lives more than ten years in captivity; but gives two unusual examples of survival to fourteen and eighteen years—a limit considerably exceeded by the Trivandrum specimen.

Cheek Bones of Teleostomes

TAKING the sensory organs of the lateral line as a criterion, T. S. Westoll (*J. Anat.*, 71, Pt. 3; 1937) has endeavoured to clear up the confusion that exists in regard to certain of the cheek bones in teleostome fishes. In recent years, it has been shown that the bone in the most primitive tetrapods which is homologous with the mammalian squamosal is associated with the horizontal part of the jugal canal. This provides a starting-point from which to work backwards to the fish. It is found that in the Choanata generally, allowing for modifications resulting from the adoption of different feeding habits, a squamosal bone can be recognized to be lost perhaps only in certain late dipnoans. On the other hand, in all known Actinopterygii the canal has degenerated, and in consequence the squamosal bone has disappeared.

Decapod Crustacea of Japan

A ZOOGEOGRAPHICAL survey of the decapod Crustacea of the Seas of Okhotsk and Japan carried out by Z. I. Kobjakova shows that in both areas boreal forms predominate to the extent of up to seventy per cent of all the decapod species occurring in the seas (*Trav. Soc. Nat. Leningrad*, 65, 185; 1936). Next in order follow the arctic-boreal forms, followed by subtropical, and the poorest representation, particularly in the Japanese Sea, is of true arctic species. In this Sea there is no abyssal fauna, because of the shallowness of the straits, and the history of the Sea, which to the close of the Pliocene was an inland sea separated from the Pacific by a strip of land, is also that of a shallow basin the floor of which has sunk up to 4,000 metres only in recent times. The isolation from the Pacific accounts for the large number of endemic forms (21 per cent of *Macrura*), for the smaller number of Pacific forms, and partly for the influx in relatively large numbers (12.3 per cent) of typical southern sub-tropical and even tropical forms. The decapod fauna of the Japan Sea is richer (113 species) than that of the Sea of Okhotsk (81 species), but in the latter there is a true abyssal fauna derived from the Pacific Ocean; on the other hand, southern sub-tropical representatives are much fewer in number.

The Millipedes of India

No. 4 of vol. 11 of the *Memoirs of the Indian Museum* (1936) consists of a long memoir by Dr. C. Attems of Vienna on the Indian Diplopoda. Under the term "India" are included the whole of the Indian Peninsula, Ceylon, Burma, Indo-Chinese countries and China, excepting the Malay Peninsula. The author states that systematic and faunistic knowledge of the Indian Diplopoda is still very incomplete, and in fact we are only at the beginning of a faunistic explanation. In the present paper, 62 new species and 15 new genera are described. The most characteristic feature of this fauna is the great number of Sphaerotheridæ present, all the genera, excepting *Zephronia*, being endemic. Altogether, 290 species and subspecies of Diplopoda are known from the region dealt with and, excepting five, they are all endemic. Of the 92 Indian genera, 64, or nearly 70 per cent, are endemic. Only South India can be

regarded as at all properly explored with reference to these animals, while China, with only 21 known species of Diplopoda, is least explored of all. Dr. Attems's contribution is likely to remain as the basis for the study of the oriental Diplopoda for many years and is, consequently, a work of importance to all students and workers on that class of myriapods.

Classification in the Amaryllidaceae

THE four genera of the Amaryllidaceae, *Zephyranthes*, *Pyrolirion*, *Hippeastrum* and *Habranthus* have been encumbered with a confused taxonomy for the last fifty years. Their numerous species have made an ever-increasing contribution to garden beauty, and it is therefore most fortunate that Mr. J. R. Sealy has recently reduced their classification to order (*J. Roy. Hort. Soc.*, 62, Pt. 5; May 1937). Characters of the spathe, the androecium and the gynoecium, have confirmed Dean Herbert's original descriptions of the four genera in 1821, and discount more recent tendencies to include them in two groups. The outlook of the paper is that of a 'splitter', but the descriptions now given are exact and clearly defined. They should effect the exact correlation of the name of a plant species with its degree of beauty or utility, which is the necessary contribution of taxonomy to horticulture.

Rust-Resistant Antirrhinum

THE severe attack of antirrhinum plants by the rust-fungus *Puccinia antirrhini* in 1934, turned the attention of gardeners to possible methods of control. Mr. D. E. Green has shown that the fungus cannot reasonably be kept in check by fungicides, and he has recently described his trials with resistant plants (*J. Roy. Hort. Soc.*, 62, Pt. 5; May 1937). A number of strains of the antirrhinum of American origin have been found to possess varying capacities for resisting attack by the rust fungus. The best of them is 62 per cent resistant; but resistance is not as yet combined with horticultural excellence. The attainment of such a combination presents the urgent problem of the future.

Gold in Plant Ash

AN announcement was made some time ago B. Němec, *Ber. deutsch. bot. Gesell.*, 53, 560; 1935) that traces of gold had been found in the ash of *Sea Mays* grains from plants grown in the Žitný ostrov (the so-called Rye Island between the arms of the Danube in south Slovakia). Danube sand from this district is known to contain gold (about 0.1 gm. per ton) and plants are able to accumulate it. According to analyses, the metal concentrates in the seeds and fruit of flowering plants, whilst the whole plant of *Equisetum palustre* is found to accumulate gold to the extent of 610 gm. per ton of ash. It is found that the gold content is related to the silica content of the ash. Among the ashes examined the following percentages of gold were recorded:

<i>Sea Mays</i> (fruit)	0.00015-0.0002
<i>Urtica dioica</i> (plant)	0.00168
<i>Datura Stramonium</i> (fruit)	0.00202
<i>Helianthus annuus</i>	—
<i>Monarda arvensis</i>	0.030
<i>Chenopodium vulgare</i> (stem)	0.011
" (fruit)	0.06
<i>Salix caprea</i> (wood)	traces

Plants grown at other places where gold has been found were also found to contain recognizable amounts of the metal in the ash, but none was found in the

same species grown where gold was known to be absent. The metal was first detected by its reaction with dimethylamino-benzylidene thiocyanate, and later some of it was actually isolated by reduction and fusion into an ingot. Prof. Němec, in collaboration with Drs. J. Babička and I. Smoler, on February 27, read before the Czech Academy of Sciences a paper on the spectroscopic identification of gold in these plant ashes and gave further chemical evidence of the accumulation of the metal in the ashes of many plants growing in auriferous soils. The spectrograms are said to confirm the presence of gold in those plants in which the metal was detected by chemical means.

Geological Aspects of Deep Drilling Problems

THERE are three main differences between drilling a deep well and an ordinary well to a depth of only two or three thousand feet: in a deep well, the distance between points of development and application of mechanical power is increased, and temperatures encountered are higher and pressures greater. W. E. V. Abraham, in a paper presented to the Burma Branch of the Institution of Petroleum Technologists on May 4, considered the geological aspect of these three differences. The increased length of transmission shaft is on the whole an engineering problem, though geological forecasts as to depths at which particular horizons will be met are correspondingly less certain at greater depths; the strata drilled through are liable to be harder, tougher and more compact, and coring is a more difficult operation at depth. A point of interest to the geologist is that the depth/temperature gradient varies in different places depending on the nature of the strata encountered, that is, whether folded, synclinal or anticlinal. Sufficient data are not, however, available for the formulation of any theory of temperature/gradient variation. Other problems resultant upon increased temperature are concerned chiefly with cementation and mud control, and do not therefore come within the purview of the geologist. Increased pressure with depth, however, concerns the geologist vitally, and the problem is no simple one, since it has been proved that as a general rule fluid pressures do not increase in accordance with the corresponding hydrostatic head, but in some cases, after a certain depth has been reached, are more than twice the corresponding hydrostatic head. Several theories have been advanced to account for abnormal pressures encountered at depth, all of which are based on the assumption that free movement of the fluid is in some way prevented, with the result that high pressures are incapable of dissipation. The most probable cause of such abnormal pressures seems, on the evidence now available, to be the weight of overlying strata.

Hydrography of the River Severn

THE flow of the River Severn during the fifteen years 1921-1936 was the subject of a paper read before the Institution of Civil Engineers on April 20 by Prof. S. M. Dixon, Mr. G. Fitzgibbon and Dr. M. A. Hogan and now published. The Severn was selected for the purpose of flow investigation because it was the only large river free from artificial controls and river traffic within convenient distance from London. The portion of the Severn Valley dealt with lies above Bewdley and has an area of 1,632 sq. miles. The present course of the river seems to be the result of glacial action, and there are indications

that the pre-glacial valley ran northwards and is now covered by drift. It seems possible that a considerable quantity of water may be lost to the river by percolation along the direction of its old channel, particularly at low stages of flow. After discussing the selection of gauging stations, the methods of discharge-measurements and their accuracy, the paper (as reported in the *Journal of the Institution of Civil Engineers*, No. 7, 1936-37, June 1937) gives the results in graph form of 59 discharge measurements carried out during the years 1925-32 and one flood discharge in 1922. The largest discharge, 17,400 cusecs, was measured at the Elan Aqueduct bridge on December 11, 1929. Daily discharges for each of the fifteen years covered by the records have been plotted as hydrographs, of which five selected examples have been filed in the Institution library. Hydrographs of two floods (May 31-June 1, 1924 and February 16-22, 1928) are reproduced in the *Journal*. The difference between the average annual rainfall and the run-off (for the year commencing October 1) is 19.24 inches, or slightly more than half the rainfall. The largest loss, 23.80 inches, was in the year 1926-27, which had a high rainfall fairly evenly distributed throughout the year. The smallest loss was 18.63 inches in 1932-33, a year of low rainfall.

Borine Carbonyl

As is known, the simple hydride of boron, BH_3 (borine), has not been obtained, the simplest known hydride being diborane, B_2H_6 . A. B. Burg and H. I. Schlesinger (*J. Amer. Chem. Soc.*, 59, 780; 1937) find that a gaseous compound BH_3CO , which they call borine carbonyl, is obtained by the interaction of B_2H_6 with carbon monoxide in great excess and under pressure. The reaction reaches equilibrium rapidly at 100° ; at room temperature the reaction is slow enough to permit the isolation of the product: $B_2H_6 + 2CO \rightleftharpoons 2BH_3CO$. The formula was checked by the vapour density. The rate of decomposition is held to suggest the transitory existence of molecules of borine, BH_3 , but the isolation of the latter is not feasible. With ammonia, borine carbonyl forms a solid, stable at room temperature, having the empirical formula $BH_3CO(NH_3)_2$. Trimethylamine, on the other hand, rapidly and completely displaces carbon monoxide from the carbonyl at room temperature according to the equation $BH_3CO + (CH_3)_3N = (CH_3)_3NBH_3 + CO$, which is held to justify the conclusion that the reaction $BH_3CO \rightleftharpoons BH_3 + CO$ is far more rapid than the association of borine to form diborane. It is suggested that in borine carbonyl the borine and carbon monoxide are joined by a co-ordinate link consisting of electrons furnished by the carbon monoxide. The compound $(CH_3)_3NBH_3$ is remarkably stable and can be heated for some hours at 125° without showing any change in physical properties.

Response of the Ear to a Phase Reversal

C. S. HALLPIKE, H. Hartridge and A. F. Rawdon-Smith (*Proc. Phys. Soc.*, 49, 190) have studied the response of the mammalian ear to a sudden phase reversal in a sustained tone of sinusoidal wave-form. The tone was obtained from a photo-electric cell siren feeding an amplifier and loud-speaker, and an investigation with a piezo-electric microphone and cathode ray oscillograph showed that the phase reversal was present in the output from the loud-speaker. The effect of the phase reversal on a listener was that of a sudden temporary depression of the

sound intensity, sometimes accompanied by a tap or thud. The tone was then led to the ear of a decerebrate cat, and electrodes were applied to the auditory tract. The electrical disturbances were amplified and recorded. The record shows, instead of the phase-change, a temporary fall in response, which indicates that the aural elements in which these auditory tract potentials originate must be regarded as resonant structures. The electrical potentials obtained from electrodes on the cochlea were, however, similar to those from the microphone, and showed the phase change. It appears that the cochlear response originates in structures different from those responsible for the auditory tract response.

Separation of the Rare Earths

THE difficult problem of the separation of the rare earths has recently been attacked by a different method, employing the principle of distribution. Fischer, Dietz, and Jüßermann (*Naturwiss.*, 25, 348; 1937) have found that it is possible to select liquids between which compounds of the rare earths will distribute themselves, and for pairs of which the distribution coefficients of the various rare earth elements are sufficiently different to enable a separation to be made. Thus, the halides of the rare earths will distribute themselves between water and organic liquids such as alcohols, ethers, and ketones, and the distribution coefficient is different for the compounds of different elements. By the addition of other substances to the system it is possible to alter the degree of separation. The difference in the distribution coefficient of the halides of two rare earth elements differing by unity in atomic number may be as great as 50 per cent, if suitable solvents and added substances are chosen. Automatic distribution fractionating apparatus may be employed, resulting in a much more rapid separation of the rare earths than can be accomplished by the tedious methods of fractional crystallization and precipitation.

A New Harmonic Analyser

THE problem of harmonic analysis arises in many connexions, and the labour of the arithmetical methods is such that several attempts to devise machines for the evaluation of Fourier coefficients have been made. An essential element of them all is, of course, some form of mechanical integrator. Henrici built several models, of which the last enables ten coefficients to be obtained in one operation, from a curve which is followed by a tracing point. A purely electrical instrument has been developed by Prof. Miles Walker and his collaborators which enables harmonics of a voltage or current wave to be separately determined; the integrator in this instrument is a watt-meter. A new instrument, designed by Mr. J. Harvey, of the Imperial College, made by Amslar, and of which an example has recently been added to the mathematical collection in the Science Museum, uses as the integrating device an ordinary planimeter wheel. The various harmonics are determined separately, each order by means of a separate, interchangeable pinion. Harvey's original model went only to the sixth order, but Messrs. Amslar, by added gearing, and without alteration of principle, have extended this number to ten (21 coefficients). With this instrument, results to an accuracy within 1 per cent can be obtained. The instrument can also be used to find areas and their first and second moments.

Development in International Geodesy*

By Dr. J. de Graaff Hunter, C.I.E., F.R.S.

THE increase in the scope of geodetic work accomplished in recent years and planned for the early future is remarkable. The fundamental problem of geodesy is the precise determination of the shape and dimensions of the earth, or what may be described otherwise either as the figure of the earth or the form of the geoid. When this is fully solved, benefits will accrue to geophysics as well as to geodesy.

In the nineteenth century, Colonel Clarke derived values of the elements of the terrestrial spheroid, first in 1866 and later in 1880. In 1866 Clarke used several meridian arcs, namely, Anglo-Gallic 39° – 60° N., Russian 45° – 70° N., Cape 34° – 29° S., Peruvian 3° – 0° S.; and both of Clarke's determinations are utilized in one or other of the great geodetic surveys. They may be considered as the best of those made simply from arcs of triangulation; but all such deductions are vitiated, more or less, by deviations of the vertical. In 1909 Hayford derived a new set of values from the triangulation of the United States, introducing the hypothesis of isostasy so as to avoid the effects of anomalous deviation of the vertical; and his figures were adopted by the International Union of Geodesy and Geophysics in 1924 at Madrid as defining the international spheroid.

Now we are entering a new era. The figure of the earth can be determined either from triangulation arcs or areas, or from gravity surveys; or from a combination of both. The greater the extent of the work of either kind, the higher is the precision which may be looked for in the results, which also become more detailed. In the first method, the weakness of determination has derived from the relatively small scope of the data. Thus Clarke's determination of 1866 was based on a few arcs of meridian of total amplitude less than 60° ; while Hayford's determination rested on an area which is less than two per cent of the earth's surface. Later determinations from the gravity field have also suffered from incompleteness of data. It is in the direction of greater fullness of data that a remarkable change is taking place; and this change is rendered possible and being brought into being by the Union of Geodesy.

There are now triangulation projects of a very comprehensive nature. The first resolution adopted by the Union of Geodesy and Geophysics at Edinburgh contemplates the junction of European and American triangulation across Asia and the Bering Straits; for which collaboration of the U.S.S.R. in Asia, the U.S.A. in Alaska, and Canada is essential. This will lead to a longitudinal arc of no less than 316° , mostly about latitude 52° , from which it deviates for the Asia-America junction. Of this work, 188° have already been finished. There remains to be done 4,800 km. from Irkutsk to Bering, 1,400 km. thence to the Alaska-Canada border and 1,100 km. in Canada.

Work in the U.S.S.R. is proceeding apace, and a great grid of triangulation is rapidly spreading over all that territory. Not only will the work extend to Bering, but, within five years, I am informed, it

will also reach the region of Taashkent and make strong connexion through an existent link with the system of triangulation of British India. A report (of Commission 18) was presented to the Union at Lisbon on the present state and future possibilities of extension towards Australia. Already continuous triangulation exists between India and Siam and thence with French triangulation in Indo-China; and only small gaps exist between the triangulations of Siam and Malaya (four triangles) and that of the Dutch East Indies (250 km.) which extends to Sumbawa in longitude 117° E. There are possibilities of extension thence to Australia.

Again, in Europe there is already connexion between the Arctic Ocean and Crete, where there is a sea-gap of 300 km. to the North African coast. A project for spanning this is envisaged in Resolution XIV. In this or some other way, continuity will be obtained with the meridian arc, Cape to Cairo. Of this latter, of amplitude 65° , more than 60 per cent is accomplished, the main gap of 18° being in the Anglo-Egyptian Sudan. The combined system will lead to a meridian arc of 105° .

Resolution I refers also to the junction of the two Americas. At present the North American system is continuous through Canada, U.S.A. and Mexico down to latitude 17° N.

It will be seen that these schemes will lead to the ultimate connexion of all the main land areas; and it is probable that a decade will see the linking of all the main land areas of the northern hemisphere. It is much to be desired that the African arc should also be completed by that time.

Now consider the gravity surveys. Here activity has been great during the last thirty years, and there are some thousands of reliable gravity stations in various parts of the world. In 1849 Stokes showed how the detailed form of the geoid could be expressed in terms of gravity values; but we are still not in a position to obtain a full solution by this means. This is because the distribution of stations is not complete. It is essential that all portions of the globe should have a certain minimum density of stations. Lack of this cannot be made up by much greater density in special regions. Efforts accordingly need to be co-ordinated. This is well recognized by the Association of Geodesy, and a commission to consider the matter of geoidal determination was formed at Edinburgh. Most of the work required for this end is to be done at sea, though there are also land areas, some difficult of access, which remain to be dealt with. Here again we may confidently expect the situation to develop in the course of a decade, so that it will be possible to make good use of Stokes's method. The best means of combining results of this kind with those based on triangulation requires study.

The position of geodesy will be entirely changed when all geodetic surveys are linked and their results expressible in correct relative terms; and this we now expect to be realized in a reasonably short time, owing to the co-ordinating activities of the Union of Geodesy.

*Report presented at the General Assembly of the International Council of Scientific Unions on April 26–May 3.

Reduction of Fading in Radio Communication

IT is now well known that part of the fading of signals experienced in radio communication is due to the variation of phase difference between the two or more sets of waves arriving at the receiver. These changes in phase difference arise in the course of transmission of the indirect waves through the ionosphere.

Two papers describing experiments demonstrating methods of reduction of this type of fading were presented early this year to the Wireless Section of the Institution of Electrical Engineers and are now available. The first paper, by Drs. A. L. Green and G. Builder, entitled "Control of Wireless Signal Variations", directs attention to the possibility, already known, of reducing variations in intensity of signals by combining the effects of two or more signals which have been transmitted on adjacent frequencies. After outlining the theory of the method, a description is given of experiments carried out between the University of Sydney and Liverpool, New South Wales, a distance of 25 km.

In this case, the fading was due to interference between the ground and ionospheric waves, and the curves accompanying the paper show that this fading could be considerably reduced by modulating the carrier wave at the transmitter, and integrating at the receiver the rectified current produced by the three sets of waves—carrier and two side-bands—so transmitted. The optimum effect is shown to be obtained when 100 per cent modulation is employed at a frequency dependent upon the path difference between the ground and ionospheric waves. A more complete control of the fading is obtained, however, if the carrier waves are suppressed, and only the two side-band waves are emitted at the transmitting station. Experiments carried out with this method have shown that fading, which under some conditions may be of the order of 85 per cent of the received signal amplitude, can be reduced to 5 per cent or less.

The second paper, entitled "Control of Phase Fading in Long-distance Radio Communication", by Drs. A. L. Green and O. O. Pulley, describes the extension of these experiments to greater distances. Measurements have been made at distances of 700 km. (Sydney-Melbourne) and 3,300 km. (Sydney-Perth) from the transmitter, and it was found that the phase fading was due to interference between two main ionospheric rays of comparable intensity. On account of the fact that the path of each of the ionospheric rays was subject to appreciable alteration during the day or night according as reflection takes place from the *H* or *F* region of the ionosphere, it was found desirable in these experiments to employ two modulation frequencies having a ratio of 3:1, the carrier wave being suppressed as previously described. The optimum control frequencies were found to be 200 and 600 cycles per second when the distance between transmitter and receiver was 700 km., whereas at 3,300 km. the best frequencies were 50 and 150 c.p.s.

The concluding portion of the first paper discusses briefly the possible application of these modulation methods of fading control to ionospheric research, to direction finding and to broadcast telegraphy and telephony. In connexion with telephony, it must be pointed out that the fading control does not apply directly to the audio-frequency components of the received waves, and a special additional modulation would be necessary to carry the intelligence. The possibility of the introduction of distortion would appear to make the application of the methods to high-fidelity broadcasting impracticable.

The investigations described in these papers formed part of the programme of the Australian Radio Research Board; in the absence of the authors, the papers were presented in London by Mr. J. A. Ratcliffe.

The Rehabilitation of British Agriculture

THE publication of the Minister of Agriculture's proposals for the assistance of agriculture in Great Britain gives greater pertinence to the three broadsheets on agriculture recently issued by Political and Economic Planning (P.E.P.). These broadsheets have been prompted by the desire to stimulate better informed discussion and the elaboration of a constructive policy in accordance with the position of agriculture in the national economy.

The first broad sheet deals with the demands of agriculture and the difficulties encountered by the various approaches to a balanced view. The Free Trade, Protectionist, Defence, Consumer and Employment approach are all briefly reviewed, as are those based on nutrition, amenities, industry, land maintenance and ownership. The broadsheet suggests that the types of crop and livestock to be produced by British agriculture should be those which the country is naturally best fitted to produce in relation to other countries over a long period. Arrangements are

necessary for the control of imports and for marketing the home output to smooth out fluctuations of supply and prevent sudden changes in prices. Subsidies or reliefs to agriculture are not objectionable in principle, provided they are open and under effective Parliamentary review and directed to the constructive development of permanent assets, not the bolstering up or development of production which is permanently uneconomic or tends to a retrograde type of farming. Great importance is attached to making British agriculture once more a flourishing industry by the achievement of superior competitive efficiency in supplying certain parts of the market. A thorough overhaul of agricultural production and marketing and of land management is required to be applied to technique in order to realize the advantages of a modern industrial structure. A parallel overhaul of country social and utility services is also required to counteract the rival attractions of factory employment and town social services.

In the second broadsheet the problem is approached from the consumer's point of view, and the need for further information about consumption habits in different areas and at different income levels as a basis for market policy is emphasized, as well as the importance of making the necessary economic adjustments to enable British agriculture to take advantage, so far as possible, of demand changes in its favour and to minimize the repercussions of other changes in demand. Needs in distribution are summarized as assembling and placing at the disposal of the consumer a suitable supply of the products demanded, at convenient times, at the lowest possible cost and at prices he can afford, and carrying out a large range of ancillary services such as delivery and credit. The value of concentrating demand where possible and of steady contracts is stressed, as well as the opportunities of developing rival industries, and the importance of efficient organization in the farming units if the good will and support of the urban electorate are to be held. The Marketing Boards have as yet scarcely touched the major problems with which they are confronted of expanding the market for home produce, increasing the return to the farmer, and reducing the cost to the consumer through savings in transport and distribution, or gaining for the farmer a larger share in the profits of processing his output or in reducing the contribution to the profit derived by supplying him with fertilizers, feeding stuffs and seeds.

The third broadsheet, dealing with the farm and of agriculture, emphasizes that the industry has far

too many diverse elements and is affected by too many other activities at home and abroad for any one formula or panacea to offer a solution of its problems. Determined criticism of all one-sided approaches or ideas is indispensable. British agriculture is also regarded as having lost the close touch with the consumer demand which it had when the market was smaller and more static. The necessity for adapting agriculture as an industry in which the landowner and land agent, the farmer, agricultural engineer, the veterinary officer, marketing expert and other specialists can effectively work together is also stressed, as well as that of continuous local leadership. A stable rural basis for agriculture can no longer be assumed, and only an all-round policy of rural reconstruction can save British agriculture as a living and growing organism. Stable prosperity for farmers, it is suggested, can only be secured by types of farm and methods of farming designed to give the maximum net return each year over a long period. Agricultural subsidies and assistance should have for their objects urgent salvage or relief work of an essentially temporary nature for badly hit branches of the industry; permanent re-adjustment of the balance between town and country life, through subsidizing of rural roads, telephones and social services; and long-term development, such as improving farms and buildings, improving stock and eradicating disease, increasing the fertility of the soil, afforestation, land drainage, and information services. Particular stress is laid on the importance of increased expenditure on research.

Bantu Blood Groups

IN a comprehensive study of the blood groups of the Bantu of Southern Africa by Mr. Ronald Elsdon-Dew (*Pub. South African Inst. Med. Research*, 7, No. 39), a suggestion is made, based on this line of research, as to the early racial history of the African peoples.

Five thousand recruits for the Witwatersrand mines, grouped according to Bantu tribal origin, were submitted to the blood test. On this evidence it would appear that the Bantu are not homogeneous from a serological point of view; but as a whole they show a position close to the origin in the predominance of *O*, a position unoccupied except by such races as the American Indian, and indicating a more primitive distribution of the groups than is found in any other black race of which the figures are known. The known crosses of Caucasoid and Negro as exemplified in Algeria and Tunis occupy a position midway between the Caucasoid races and the origin. The Berber peoples show a small proportion of *B*, but they have a proportion of *A*, which gives them a type of distribution found in certain races separated early from the stock of mankind, such as the Australian aborigines. The Bush race shows a similar arrangement, while the Hottentot lies between the black races and the Egyptians.

The Southern Bantu are found to fall into three main groups, a primitive group, an intermediate group and a Caucasoid group. In the Caucasoid group fall the Mpondo and Xhosa. In comparison with other groups, this must have absorbed a con-

siderable proportion of Caucasoid blood. The Bushman-Hottentot complex could have had this effect, and this agrees with the fact that Mpondo and Xhosa show culturally and linguistically the results of Bushman-Hottentot contact to a greater extent than is shown by the other races. The intermediate group comprises Zulu, Shangaan, Tswana and Southern Sotho, corresponding roughly to the Nguni group. The primitive group comprises on one hand the Tshopi and Inyambane, about whose separate entity there is no doubt, and on the other hand the Swazi and Northern Sotho, whose position needs further investigation with reference to the Bantu as a whole, and the alleged primitive black race. If, as is usually held, the Bantu is derived from a Negro stock with Caucasoid (Hamitic) admixture, it is remarkable that serologically it should be more primitive than the Negroes of West Africa, a fact which suggests to the author a revision of early African racial history.

At some early date Africa was inhabited only by a black race, probably living near the west coast, and composed solely of the *O* group, as *A* and *B* had not appeared at the time it separated from the main stock. Africa was then invaded by a light-skinned small race bearing the factors *B* and *A*, which moved south, forming the Bushmen. A taller, light-skinned race with the factors *O* and *A* then arrived, but remained in the north, forming the Berber race. Then came a race with all the blood-groups which

spread all over Africa, pushing the Bushman south and giving rise to the Hottentôts. The black race, still unaffected by *A* and *B*, moved south, following Bushmen and Hottentot and followed by other races with all the groups, who affected the black left behind in West Africa and the rearguard.

The Bantu are thus the result of the interactions between the Caucasoid and a primitive black race showing little or no *A* and *B*. Serologically they are more primitive than the Bushman, while if the Hottentot has had any effect it is only in recent times.

Excavations of the Egypt Exploration Society in Nubia, 1936-37

AN exhibition of archaeological finds by expeditions sent out by the Egypt Exploration Society at Tell el-Amarna and Sesebi on the Upper Nile in Nubia in the season 1936-37 opened in the rooms of the Palestine Exploration Fund, 2 Hinde Street, Manchester Square, London, W.1, on July 5, and will remain open until July 24.

The excavations in Nubia, which have been carried out under the direction in the field of Prof. A. M. Blackman, were undertaken in view of the approaching termination of the Society's operations at Tell el-Amarna, and in the expectation of obtaining a view of the culture of that period at an angle differing from that of the Amarna evidence. Sulb and Sesebi, sites covered by the concession granted to the Society by the Government of the Anglo-Egyptian Sudan, have been known since 1908 to be associated with Akhenaten, when the late J. H. Breasted identified Sesebi with the Nubian Gem-Aten, and recognized that the founder of the temple there had been Akhenaten, and not, as previously supposed, Sethos I, who had covered the inscriptions of the earlier king with plaster and inscribed on them his own name and a rededication of the temple.

Although the official name of the city was doubtless changed after the time of Akhenaten, the former name must have been retained among the people, as it was still known by that name seven centuries later, when the god of the place was recorded as "Amun of Gem-Aten".

The temple was founded about 1370 B.C., before Amenophis IV had changed his name to Akhenaten, as is shown by the foundation deposits. This change took place about the fourth year of his reign, or at Sesebi, owing to its remote situation, perhaps a little later. Scarabs of Tethmosis III and Tethmosis IV from the cemetery suggest that Sesebi was an Egyptian settlement of some importance long before the accession of Amenophis IV.

The fortified town of Sesebi is situated between the Second and Third Cataracts of the Nile, about one hundred and eighty miles south of Halfa. The fortress, which lies about two hundred metres distant from the river on the west bank, enclosed an area of about two hundred and seventy metres long by about two hundred metres broad. Its crude brick walls are about 4.60 m. thick, and in some places still stand to a height of 4-5 m. The width of the buttresses is approximately 3.15 m. and they stand out 2.65 m. from the walls. In each of the four walls is a well-constructed gateway.

Within the walls, the most striking feature is a group of three temples, before excavation thought to be one only, erected on a single and unusually solid substructure, and extending along the western side of a forecourt, once enclosed in massive walls. Four

sets of foundation deposits were found intact under the north-west and south-west corners of the substructure. They comprised among other relics two inscribed blue faience plaques and a large inscribed scarab of the same material, clearly showing that the foundation had taken place before the monarch's change of name. The full significance of this fact was brought out by reliefs on the walls of a subterranean crypt below the central temple, in which the king, sometimes with the queen, is represented seated in the company of various deities. The reliefs, therefore, belong to his polytheistic period, before he changed his religion to the monotheistic worship of the Aten. They are in the ordinary style of the Eighteenth Dynasty and not that of the Amarna period.

The crypt is in itself a remarkable discovery. It is the only known example of such a substructure at so early a date, preceding the well-known crypt of the Ptolemaic temple of Denderah by approximately thirteen hundred years.

What are conjectured to be portions of the sandstone façade of the temple, showing some highly finished reliefs, were found. Of these one shows the head of the goddess Hathor, while on another are the heads of two negro prisoners, possibly part of a much larger war relief, to which belonged a representation of the king slaying captives, not brought to England. The style of this block, with the strongly marked features and masterly line, closely resembles that of the magnificent scenes in the tomb of Horemheb. It is probably to be assigned to the end of the Eighteenth Dynasty. Mention may also be made here of a remarkable head of a granite statue of a king, or possibly of Queen Hatshepsut.

Outside the temple area an important find was a stone structure situated close to the north-east corner, which had undergone at least one reconstruction. In its original form it had been a small colonnaded open court on a stone platform about 11.70 m. square and two metres high. This had been the work of Akhenaten, and possibly was a small sun temple, a view supported by the unusual feature that it was approached by a ramp or stairway on the western side, which would enable the officiating priest to greet the rising sun on entering the temple at dawn.

Immediately south of the temple were found three rows of magazines, and south of these again the south-western portion of the residential area. In the magazines a doorjamb inscribed to a vizir of the reign of Amenophis II supports the earlier dating of the settlement.

Although the area of the town examined had been much disturbed, it produced a quantity of interesting material. It has been possible to make out the symmetrical rectangular planning of the streets.

To the west of the town lies the New Kingdom cemetery, which seems to have been subjected to considerable depredation. Tombs had been plundered, re-used and plundered again. Nevertheless, it supplied a fine collection of scarabs and much pottery, as well as other objects. Three groups included bronze mirrors laid on the chest, one a very fine specimen, and with another was a bronze bowl. A remarkable

example of fine work is a green felspar amulet in the form of a baboon with the moon-disk on its head, and probably from the same string was a *mellefiore* bead in the original gold mount. In one tomb the face painted on the cartonnage has survived. One exhibit of no little interest, though late in date, is a human pelvis still wrapped in its leather loin-cloth.

Association of Technical Institutions

SUMMER MEETING AT BLACKPOOL

THE summer meeting of the Association of Technical Institutions was held at Blackpool on June 24-26.

Two reports having a direct bearing on policy were presented and discussed. The first was the report on policy in technical education, prepared by a joint committee of the Association of Technical Institutions, the Association of Principals of Technical Institutions, the Association of Teachers in Technical Institutions and the National Society of Art Masters. First published in 1932, this report has been twice revised, in 1934-35 and in the form presented to the recent Conference. Its field is wide and includes descriptions of the present system, courses of instruction, regional co-ordination of technical education, examinations, scholarships, libraries, staffing, technical education in small towns, buildings and equipment and social activities. The second report dealt with Education for Citizenship in Technical Institutions and is dealt with in the leading article in this issue of NATURE.

Of special and immediate interest was a paper on education in industrial management prepared by Mr. E. S. Byng, vice-chairman of Standard Telephones and Cables, Ltd., and Mr. G. A. Robinson, principal of the South-East London Technical Institute. This branch of education has grown considerably of late years both in Great Britain and in the United States, and its importance cannot be underestimated. As one expert has put it: "Such training was not to be a substitute for experience. . . . The growing complexity of industrial organizations, the evolution of new techniques, the application of science to industry, the growing size of business units and such items as industrial, economic and technological factors combine to make successful management far more complicated and difficult than it was in the past. Experience plus training are recognized in all professions civil and military. Is management the only profession where training is unnecessary?" The social significance of the subject was well expressed by the authors of the paper when they said: "One of the greatest services which education in regard to management could render would be to imbue the general body of workers with a sound elementary knowledge of the principles affecting the conditions, conduct and direction of the undertaking which they serve. In a democracy, an understanding of the principles by the workers would assist management, whereas in a dictatorship the conditions may be different."

The authors further brought out the vast increase

in the number of persons who are now concerned in management. Modern manufacturing methods actually require a much larger proportion of administrative workers than was necessary under earlier conditions. In a typical engineering organization with approximately 10,000 employees, those engaged in one phase or other of management may represent as much as twenty-five per cent of the total staff. It is not to be wondered at, therefore, that many of those in control of industry feel the need for a constant supply of young men not only proficient in the technology of departmental functions, but also trained in the principles of administration. Appendices to the paper included a list of schools where instruction in management is given, and syllabuses of "Fundamentals of Industrial Administration", "Workshop Organisation and Management", and "Works Supervisory Course".

Dr. E. Benson, headmaster of the Blackpool Grammar School, read a paper on "The Grammar Schools and Technical Education". He admitted that he approached the subject from the point of view of the grammar schools. During the discussion, it was made clear that technical educationists, while differing sometimes with the educational views put forward by those connected with grammar schools, have no quarrel with grammar schools and their work as such. At the same time, they spoke their minds with some freedom when they thought the grammar schools were claiming a kind of monopoly in educational powers. Dr. Benson quoted Sir Josiah Stamp's saying that education to-day might be considered to have three main objects. It trains individuals to get a living, to live a life and to mould a world—in other words, it is education for work, leisure and responsibility. Dr. Benson's claim that the grammar school "does its best to give this complete education" may be true; but there are not lacking many who would challenge it. Neither are there lacking many who would demand to hear much more argument before they could be convinced that none of the types of post-primary schools "has succeeded so far in sharing with the grammar schools the most important of the vital qualities which the grammar schools possess. . . ." The same people would probably think that Dr. Benson had only appreciated a part of the work when to that remark he added ". . . except that junior technical schools, especially in conjunction with senior technical institutions, have, although they are comparatively few in number, established high standards for example in accuracy and craftsmanship".

University Events

BIRMINGHAM.—At the annual degree congregation held on July 3, the Chancellor (Viscount Cecil of Chelwood) conferred the honorary degree of LL.D. on the following: The Right Hon. Lord Austin, Sir Harry Gilbert Barling, Mr. Edward Cadbury, The Right Hon. Sir Wilfrid Arthur Greene, and Sir Percival Perry. The honorary degree of D.Sc. was conferred on Mr. C. C. Paterson.

The ordinary degree of D.Sc. was conferred on D. A. Howes for a treatise on "The Principles of Motor Fuel Preparation" (in collaboration with Prof. A. W. Nash) and for a paper on "The Use of Synthetic Methanol as a Motor Fuel" and other papers on allied subjects (*J. Inst. Pet. Tech., J. Soc. Chem. Ind.* and elsewhere).

The degree of M.D. (*ex officio*) was conferred on Prof. H. P. Newsholme.

CAMBRIDGE.—Dr. A. D. Thackeray, of King's College, has been appointed assistant director of the Solar Physics Observatory for five years from July 1.

An appointment to a research studentship at Christ's College will be made at the end of July 1938. Candidates must be men who will have graduated before October 1, 1938, at some University other than Cambridge, and they must be not more than twenty-six years of age on that date. Preference will be given to those who have already devoted at least a year to research. Further information can be obtained from the Master, Christ's College, Cambridge. Detailed information about the admission of research students to the University will be found in the "Student's Handbook to the University of Cambridge", published annually by the Cambridge University Press. It may be estimated that the total annual expenses, including vacations, of a research student at Cambridge, is about £350 a year.

Sir David Chadwick has been elected to an honorary fellowship at Sidney Sussex College, not at Christ's College, as stated in *NATURE* of July 3, p. 38.

EDINBURGH.—At a graduation ceremonial on July 2 the honorary degree of LL.D. was conferred on the following, among others: Prof. L. H. Baekeland, hon. professor of chemical engineering, Columbia University, New York; Sir William Bragg; Dr. N. M. Butler, president of Columbia University, New York; Sir Herbert Grierson, rector of the University; Dr. Alexander Morgan.

The Principal, Sir Thomas Holland, referred to the sense of loss felt by the University on the death of its Chancellor, Sir James Barrie, who in a letter written only three days before he was taken seriously ill, had expressed his intention of presiding at that graduation. It was at a similar ceremonial, as the Principal recalled, that Barrie was 'capped' fifty-five years ago.

ST. ANDREWS.—It has been decided to confer the honorary degree of LL.D. on the following: Prof. G. F. Stout, professor of logic and metaphysics in the University from 1903 until 1936, and Dr. W. T. Calman, president of the Linnean Society, lately keeper of the Zoology Department, British Museum (Natural History).

Science News a Century Ago

Musket's Discovery of Blackband Ironstone

DAVID MUSKET (1772-1847) was among the foremost metallurgists of his day, and besides contributing articles on iron manufacturing to the "Encyclopædia Britannica" and "Rees' Cyclopædia", he contributed some thirty papers to the *Philosophical Transactions*. On July 12, 1837, he wrote a letter from Coleford, Gloucestershire, to the editor of the *Scotsman*, in which there had been a communication on the iron trade of Scotland and the blackband ironstone. In this letter he said: "As this ironstone has now become an object of considerable national importance, perhaps you will allow me room to allude more particularly to the circumstances of its discovery. Thirty-six years ago this summer, in attempting to cross the river Calder on foot, in the Old Monkland Parishes, I obtained nearly a dry footing upon what appeared to be a continuous black pavement, from the upper edge of which I struck off a piece of substance resembling coal, which upon closer examination, was found interlaminated with yolks of brownish matter, about three-eighths of an inch in thickness. These when separated from the carboniferous schist, proved to be good ironstone, but so small in quantity, that the average of the mass did not exceed 13 per cent. Next day I returned to the black pavement, better prepared to ascertain its extent and thickness. On removing a portion of the entire bed, I found it to be fourteen inches in thickness, viz., three and a half of coaly schist with the before-mentioned yolks, and ten and a half of more compact and solid matter. . . . In a short time from making this discovery I had ascertained the existence of the Blackband in 2,000 acres of land, including the Airdrie estate (for right of working in which, to a limited extent, £12,000 a year is now to be given) and determined it to be a regular member of the coal formation. . . ."

Advancement of Medical Science

AN editorial article in the *British Annals of Medicine* of July 14, 1837, contains the following passage: "Reform in institutions is advancement in the sciences, and the latter is not the least deserving attention at the present time. Our practice is based on physiological indications, and much of the current physiology is false; in this country it is not yet on a line with the actual state of the science. We have too much metaphysical reasoning about functions and about diseases, too little systematic observation. . . . Could not the Association encourage the invention of some systematic form by which the observations of a great number of members may be collected and compared? If we are to believe a contemporary, Dr. Haviland rebuked the College of Physicians in very elegant Latin—not for their scientific apathy, not even for forgetting their mathematics, or for not applying them to vital phenomena, but for selecting fellows unversed in Latin and Greek. Better things may have been expected from Dr. Haviland, but it is as difficult for an Oxford and Cambridge professor as for an Irvingite to raise his thoughts above the 'tongues'. The University of London will, we understand, reduce languages to their subordinate place as instruments in the general scheme of education."

Thomas Graham at University College, London

ON July 15, 1837, the *Mechanics' Magazine* said: "The Chemical Chair of the London University College, vacant through the lamented demise of Professor Turner, has been conferred on Mr. Graham, the Andersonian Professor of Chemistry at Glasgow. A better selection could scarcely have been made. Mr. Graham was first made favourably known to chemical philosophers by his discovery of the laws of gaseous diffusion. He established by well-devised experiments, the conformity of gases flowing through minute orifices, to the universal physical law that determines the issuing velocities of non-elastic fluids. During the last five years he has been diligently engaged in elaborate inquiries into the constitution of salts, with special reference to the functions of their watery element, and has already published some results that are considered by good judges to affect materially the higher doctrines of chemical philosophy."

Medical Schools in Russia

THE issue of the *London Medical Gazette* of July 15, 1837, contains the following account of the contemporary medical schools in Russia: "There are three principal universities in Russia proper, those of Moscow, Harkoff and St. Petersburg; and each of these universities has a large school of medicine. Those of Moscow and St. Petersburg are the most considerable, but there is still a good school at Harkoff, situated in the southern part of the empire, and destined for the convenience of the nations of the conquered provinces on the Asiatic borders. Each university which has a faculty of medicine has also an institute of medicine of the same kind; the students who attend the latter are educated at the expense of the Government, and are subsequently obliged to serve six years, at least, in the civil or military service. Although the first rudiments of a medical school at St. Petersburg are to be found in the establishment of the naval school by Peter the Great in the year 1715, yet the merit of organizing a medical faculty is due to Catherine the Second. In 1764 the Empress founded a medical college which with but few alterations from its first instalment is still recognised in the Medico-Chirurgical Academy of St. Petersburg. To the jurisdiction of this institution were subjected then, as at present, all the medical institutes and all medical practitioners, with the exception of court physicians, in the Empire."

Ploughing by Steam

THE issue of the *Gentleman's Magazine* of July 1837 contains the following announcement: "A very successful and interesting exhibition of ploughing by steam, invented by Mr. Parkes, took place at Red Moss, near Horwich, Lancashire. The engine is not locomotive, but remains stationary while the plough is at work. The plough is set in motion by means of two long, flexible belts of iron, revolving round two wheels attached to the engine, and round another wheel in a frame firmly fixed on the moss, at such a distance from the engine as may be proposed to make the furrow. The ends of these belts are fixed to the two ends of the plough, and pull it to and fro, for it does not turn in working, but cuts a furrow both when it recedes from and returns to the engine. This operation is most satisfactory, the plough turning a furrow eighteen inches broad, nine inches thick, and more than 300 yards long in less than four minutes."

Societies and Academies

Dublin

Royal Irish Academy, April 12.

P. G. GORUMLEY: The zeros of Legendre functions. The number of zeros of the function $Q_n^m(x)$, n and m being real, is determined by considering the change in phase due to a complete circuit round the plane, the number which are situated on each axis being given. Those zeros of the function $P_n^m(z)$ which lie to the right of the imaginary axis are considered.

A. C. FORBES: Some climatic theories in connexion with tree remains in and under peat. The stump layers in lowland bogs, which various observers from Geikie onwards have attributed to secular changes in rainfall, merely represent vegetative features in the development of marsh peat. They are the remains of trees which originated, matured and died on a saturated or water-logged substratum induced by topographic features, and neither normal nor periodic fluctuations in rainfall could have affected them to any material extent as is shown by their characteristic root development. The stump remains under mountain (soligenous) peat represent the final generations of pine and birch which gradually disappeared at high elevations, resulting in forest being replaced by peat, which, in its turn, is disappearing above 2,000 feet or so. These changes must be correlated with lower temperatures during the growing season, and the general tendency during the last 2,000 or 3,000 years in the British Isles has apparently been in the direction of cooler and moister summers and milder winters, and the altitudinal tree limit during that period has been lowered to about 1,000 feet. The rainfall and temperature conditions for peat formation are still in operation at the lower levels, and these do not differ in any important respect from those necessary for forest growth.

Paris

Academy of Sciences, May 19 (*C.R.*, 204, 1449-1516)

JULIUS DRACH: The logical integration of linear differential equations.

NICOLAS KRYLOFF and NICOLAS BOGOLIOUBOFF: The ergodic properties of series of probabilities *en chaîne*.

SOLOMON MANDELBOJT: A general theorem furnishing the argument of singular points situated on the circle of convergence of a Taylor's series.

JACQUES HADAMARD: Remarks on the preceding note.

RAOUL GOUDRY: Measurements of the intensity of gravity in France during the year 1936. Results for the values of g at fifty stations in France carried out with the Holweck-Lejay instrument.

VICTOR VOLKOVISKI: Vortices in bands in liquids.

ANDRÉ GUILBERT: The elementary expression of the energy affecting a magnetic particle of very small dimensions in a magnetizing field.

RAYMOND HOGART and MAURICE FALLOT: The identification of various phases by magnetic study and by the X-rays in alloys of iron and palladium. The magnetic study showed two phases the approximate composition of which are FePd and FePd_2 , and these were confirmed by the X-rays. The phases only appear after prolonged annealing.

BOBIS VODAB: The absorption spectrum of nitric oxide (NO) in the liquid state.

MILKA MILKA RADOCHITICH: The influence of the solvent on the absorption spectra of neodymium acetylacetonate. Summary of results obtained with

39 organic solvents. Neither the dielectric constant nor the electric moment afford an explanation of the results. These intervene, but there are other factors which complicate the comparisons.

Mme. NIUTA WINTER-KLEIN: The relation which exists between the temperature of transformation and the variation of the (refractive) index for several kinds of glass.

W. BRONIEWSKI and I. ST. GLOTZ: The physical and mechanical properties of pure iron as a function of the cold hardening.

LOUIS HACKSPILL and ANDRÉ BOROCOO: Compounds of the isotope 2 of hydrogen with the alkali metals (alkaline deuterides). The alkaline deuterides can be obtained by synthesis under the same conditions as the hydrides, their formulae are analogous with the latter, and their appearance is the same.

MARTIN BATTAGAY and PIERRE BOEHLER: The anthrylthiocyanates, anthrothiazols and mercaptoanthrothiazols.

MARCEL FRÉREJAQUE: Acetylglucosides of amines and rotary power.

RAYMOND PAUL and HENRI NORMANT: The action of furfuryl bromide on sodium phenate, *o*-furfurylphenol and furfuryloxybenzene.

A. A. ISAKOVA: The true influence of bacteriorhizal micro-organisms on the germination of seeds (2).

A. V. IVANOV: A new ectoparasitic mollusc of the genus *Megadenus* Rosen.

T. A. BEDNJAKOVA: Induction of the infundibulum by the anterior end of the chorda.

Washington, D.C.

National Academy of Sciences (Proc., 23, 189-250, April).

C. E. NURNBERGER: Ionization theory and radiobiological phenomena. Assuming that hydrogen is the chief absorber in biological materials of neutrons, the ejected protons are the cause of the major part of the ionization. The concentration of ions produced by protons, and also by α -particles, is more than a hundred times that produced by electrons, and irradiation of aqueous solutions of tyrosine with X-rays (Stenstrom and Lohmann) and with α -particles gives results supporting the view that the chemical changes produced depend on ionic concentration. The relation of this work to recent investigations of the 'selective effect' of neutron irradiation of tissues is discussed.

A. A. BLISS: Effects of the length of X-ray waves on seeds. For moderate dosage, two minutes' exposure gives optimum growth at one stage, while at a later stage, optimum growth is produced by a different exposure. Over the range 0.6-0.12 Å., the effects seem to be independent of wave-length.

M. MUSKAT and E. HUTCHINSON: Symmetry of the transmission coefficients for the passage of particles through potential barriers. A general wave-mechanical proof.

P. W. BRIDGMAN: Polymorphic transitions of inorganic compounds to 50,000 kgm./cm.². Thirty-five, out of eighty-five, such substances show polymorphism, and the transition parameters (pressure, temperature, change of volume and latent heat) have been determined. The temperature range of the experiments was -79° C. to 200° C. The ice-type of transition (stable phase at higher temperature has the smaller volume) tends to become more common at high pressures. Latent heat shows no statistical trend with increasing pressure, but the energy change tends to increase proportionally with pressure, leading to the view that the atoms increase in size on passing to the high-pressure form. This suggests that an important fraction of the electrons of the high-pressure form are in an essentially different state from that in the free atoms.

G. H. PARKER: Colour changes due to erythrophores in the squirrel fish, *Holocentrus*. This fish changes from red to white in about 6 sec., and from white back to red in about 10 sec., on transfer from a black-walled illuminated vessel to a white-walled one or the reverse, due to expansion or contraction of red pigment in the erythrophores. Cutting through

nerves supplying the skin suggests the existence of dispersing and concentrating nerves; the latter, at least, are activated by a neurohumor soluble in lipoids.

F. B. SUMNER and P. DOUDOROFF: Some quantitative relations between visual stimuli and the production or destruction of melanin in fishes. Colour adjustment of fishes and amphibians to background depends on (1) dispersion or concentration of pigment in chromatophores (rapid), (2) changes in amount of pigment (slow). This paper deals with the latter. Fish were placed in two series of four tanks painted white, grey, dark grey and black respectively, one set being illuminated by two 200-watt lamps, the other by two 10-watt lamps. After 87 days, the melanin contents of fish from each tank was estimated photometrically.

R. GOLDSCHMIDT: A remarkable parallelism. In investigating the mutant 'vestigial' in *Drosophila* and its series of multiple alleles, it has been found possible to arrange them in a series with increasing degeneration of wing tissue. It is thought that the genes control the production of a growth-promoting substance, and that the different alleles produce an insufficiency which, below a certain threshold, causes degeneration. Representing the data graphically, the curves produced are identical with those of Krueger on the relationship of bacteria and phage, indicating that the kinetics of the two processes are the same.

E. W. SINNOTT: The relation of gene to character in quantitative inheritance. If the distribution as to a given quantitative trait in an *F*₂ population is symmetrical, it is concluded that each gene makes a constant absolute contribution and that the contributions are cumulative; if, on the other hand, the distribution is skewed, this is considered as evidence that the genes are interacting and producing a geometric or multiplicative effect. Experimental work on fruit size in *Cucurbita Pepo* favours the latter view.

S. HINCH: The instantaneous visual threshold after light adaptation. In 1918, J. Blanchard published data on these thresholds. The eye was adapted to a given intensity by looking at a large illuminated area. At a given moment the adapting light was cut off and the minimum illumination required to make visible a central area at the same moment was determined. These data can be explained on the duplicity theory (cones functioning at high intensity and rods at low intensity), and numerical details of the data conform to the mathematical predictions of a photoreceptor process consisting of (a) a primary photochemical reaction whereby a photosensitive material is converted into active products, (b) a primary dark reaction maintaining the supply of photosensitive material, (c) a secondary dark reaction in which products of (a) undergo a change providing an impulse to the attached nerve.

G. A. MILLER: The groups of order p^m which have $m-1$ independent generators.

R. BRAUER and C. NEUBITT: Regular representations of algebras.

N. JACOBSON: Simple Lie algebras of type A.

D. V. WIDDER: The iterated Stieltjes transform.

K. MÄNGER: Metric methods in calculus of variations.

S. PARTENACK: The mean value of r^2 for Keplerian systems: a correction.

Forthcoming Events

INFORMAL CONFERENCE ON "CONDUCTION OF ELECTRICITY IN SOLIDS", July 13-16.—Arranged by the Physical Society and the University of Bristol, to be held in the H. H. Wills Physical Laboratory, University of Bristol.

Tuesday, July 13

SOCIETY FOR THE STUDY OF INHERITANCE, at 4—(at 11 Chandos Street, Cavendish Square, W.1).—Mrs. Lillias M. Blackett Jeffries: "Marriage in Relation to Alcohol and Drug Addiction".

Wednesday, July 14

BRITISH ACADEMY, at 5.—Dr. Paul Schrecker: "Leibniz: with Special Reference to his Views on International Relations".

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

ENGINEER at the Fuel Research Station, East Greenwich.—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (quote J. 37/10) (July 12).

LECTURER IN MINING in the Chesterfield Technical College.—The Clerk to the Governors (July 14).

LECTURER IN ELECTRICAL ENGINEERING in Armstrong College, Newcastle-upon-Tyne.—The Registrar (July 16).

LECTURER IN MECHANICAL ENGINEERING in the Northampton Polytechnic, St. John Street, N.C.1.—The Principal (July 16).

RESEARCH CHEMIST with the Bone Research Association.—Prof. W. A. Bone, Imperial College, South Kensington, S.W.7 (July 16).

LECTURER IN VETERINARY PHARMACOLOGY, LECTURER IN VETERINARY PARASITOLOGY, and LECTURER IN ANATOMY OF DOMESTICATED ANIMALS in the Department of Agriculture, I.F.S.—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (July 16).

LECTURER IN MATHEMATICS and LECTURER IN CHEMISTRY in the Kingston Technical College.—The Principal (July 17).

ASSISTANT (grade III) in the Signals Experimental Establishment, Woolwich, S.E.18.—The Superintendent (July 19).

LECTURER IN CHEMISTRY in the University of Birmingham.—The Secretary (July 21).

ASSISTANT CHEMIST in the Biochemistry Section of East Malling Research Station, Kent.—The Secretary (June 23).

DIRECTOR of the All-India Institute of Hygiene and Public Health, Calcutta.—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (July 24).

PRINCIPAL of the South-West Technical College, Walthamstow.—The Director of Education, County Office, Chelmsford (July 24).

LECTURER IN HORTICULTURE AND NATURE STUDY in the Stranmillis Training College, Belfast.—The Principal (July 29).

GEOLOGISTS in the Geological Survey of Great Britain and Museum of Practical Geology, Exhibition Road, South Kensington, S.W.7.—The Director (July 31).

STRUCTURAL ENGINEERING DRAUGHTSMEN in H.M. Office of Works.—The Chief Architect (Ref. G. W. Street), Room 131A, iv. Flr., H.M. Office of Works, Storey's Gate, S.W.1.

LECTURER IN CHEMISTRY in the Brighton Technical College.—The Education Officer, Education Office, 54 Old Steine, Brighton 1.

HEAD OF THE MECHANICAL ENGINEERING DEPARTMENT in the Croydon Polytechnic.—The Education Officer, Education Office, Katherine Street, Croydon.

Educational Equipment for the New Age

THE address on the university in civic training, which General Smuts delivered at his installation as Chancellor of the University of Cape Town on March 2, did not receive the attention it deserved outside South Africa. It dealt with a theme which has recurred in many speeches since it was stressed by Sir James Barrett and others at the celebrations of the centenary of the University of London last year, and at the Conference on Academic Freedom at Oxford in 1935. The function of the university, General Smuts insisted, is not merely to give its students a professional qualification; it is to impart the ideals of citizenship and to fit its graduates spiritually into the world in which they had not merely to earn their living but also to play their part worthily. The university must teach the humanities—the things which furnish the student with the larger human equipment for life.

University and humanity together should form the keynote and essence of university culture, and it is in their absence that we suffer from excessive specialization and the narrow outlook responsible for so much mischief and suffering in the world to-day. Universality in its nature implies freedom from the prejudices which arise from ignorance or narrowness of outlook; it means also an impartiality, a willingness to learn and a curiosity to understand whatever life may hold for us. No less than the ordinary citizen does the university student need to avoid a single-track mentality, and his university training should give him above all a vision of harmony in the universe, of the principles of order and beauty, which should remain with him as the most satisfying and outstanding experience of his life. Science, philosophy, poetry, religion can all help to clarify and deepen that experience.

The greatest lesson that science can teach us, General Smuts urged, is respect for facts; and in the present-day tendency to follow slogans or catchwords, to worship ideologies or exalt party politics unduly, a disinterested loyalty to facts is the sovereign remedy. Equally important with this impartial spirit of science is the urbane generous spirit of humanity; and General Smuts believes that the hostility of rival fascist and communist systems to the principles of racial, religious and political toleration is a passing phase, a symptom of the confusion and unrest of the times. He urged that South Africa, more than any other country in the world, is a great human laboratory, where experiments in racial co-operation are essential to success.

If it is difficult for European onlookers to feel as confident as General Smuts of either fascism or communism learning the grace of toleration or respect for facts, his plea for universality and humanism undoubtedly will meet with a widespread response. Its force was undoubtedly recognized, for example, in the discussions at the symposium on the chemist in industry in Manchester last April, where the need for a wide outlook and high ideals, as well as technical or professional efficiency, was stressed by Prof. J. C. Philip. Here again the evils of over-specialization were discussed, though it was pointed out by Mr. F. Scholefield that this danger does not lie in the kind of subject chosen for special study, and that men can be trained for a specific technical occupation, without incurring this evil, if the training is given on right lines.

That these dangers should be recognized is all to the good, but the discussion referred to, at which much was said about the qualifications of the chemist for administrative posts, scarcely stressed

sufficiently the social responsibilities of industrial management at the present time. The growing tendency for industrial efficiency to be considered not merely in terms of dividend-earning capacity or mechanical efficiency but also in relation to industrial welfare and service to the community, enhances the importance of industrial leadership having not merely high ideals and wide sympathies but also some real understanding of social problems. The industrial leader must have the wisdom of a good citizen.

The special responsibilities of the universities in this matter have been frankly recognized of late. They were stressed in the report of the University Grants Committee as well as at the Quinquennial Congress of the Universities of the Empire at Cambridge last July, and the part which the universities have played in the social surveys of the Special Areas as well as the expansion, for example, of the Economics Research Section of the University of Manchester, indicates a desire to make a practical contribution to social science and the solution of social problems on a growing scale.

Important as are these practical studies and investigations, the fundamental problem for the universities in this matter is that to which General Smuts directs attention and on which Sir Ernest Simon challenged them in an address at Cardiff last year. If the universities adequately fill their function of providing leaders and citizens who will give a wise lead to their fellows in the effort needed to eliminate weak spots in our public life and to build a better social order, the redistribution of effort in scientific research or its initiation in new fields will follow. Moreover, effective leadership in a democracy demands a measure of co-operation and understanding from its ordinary citizens which in turn requires far higher intellectual qualities than in the authoritarian State, and here again the university has responsibilities scarcely less important than in the provision of leaders.

The two problems are in fact inextricably linked. Unless the university can provide democracy with leaders capable of taking wide and disinterested views and forming sound judgments in public affairs, and of clear and critical thinking, and able to use the appropriate scientific method of thought in the complex affairs of human society, the challenge of the authoritarian State to-day can scarcely be met. Equally the university cannot be expected to provide such leaders unless the students entering its doors have received a sufficiently wide general training in human and

cultural subjects for the university to impart that stimulation and enrichment of the whole mind, independent of any specialized study the student pursues, which enable him to lead a fuller and more interesting human life and to play more adequately his part as a member of the community. Again, unless the training of the ordinary citizen in general science, in social subjects and in public affairs is wide enough to fit him to take disinterested views, to form sound judgments and to recognize and prefer wisdom and integrity in public representatives to the arts of the humbug and the demagogue, even if the supply of competent leaders is adequate, their selection by a democracy is not assured.

The heart of the problem lies accordingly in the pre-university training, especially in the post-primary or secondary school. Only as this is adequate and broad enough can the universities fulfil their own special functions of providing men and women, not merely skilled in some special subject or branch of knowledge but distinguished by a sense of values, a wide outlook, moral courage and a capacity for creative thought which, when ripened by experience, can be at the service of the community in any of the problems with which they may be confronted in their professional, industrial or civic life.

The question of training the university graduate for participation in public affairs cannot therefore be seriously considered apart from the question of educating the community as a whole. Sir Ernest Simon's insistence that the inefficiency of transfer of training implies that citizenship cannot be taught incidentally or indirectly, but that it can only be learnt by the direct study of the thought and life and actions of men in society, while undoubtedly right, should not lead us into any attempt to graft a special course of training in citizenship into the existing curricula of universities. The basic knowledge in these matters must be acquired at school. The university may incidentally extend that knowledge in certain subjects, but its main function here must be to supply the corrective to specialization, to quicken interest in human, social and cultural values, to inspire a vision of life as a whole, and to send out its graduates with a real interest in the affairs of the world, with a standard of values, a capacity for thinking clearly and some knowledge of the more difficult aspects of the problems of citizenship.

None the less, the university has certain special responsibilities in this field. In the first place, the need for developing some effective corrective to

the present excessive and premature specialization is urgent and long overdue. Society cannot afford to wait until the universities are receiving students much more adequately prepared. Internal measures in the universities themselves are undoubtedly called for, even if only as temporary expedients.

In the second place, the influence which the universities exercise on secondary school teaching and curricula, if only through the scholarship system, is enormous. That influence could easily be exerted to repress the premature and disastrous specialization which often takes place in the later years at school. To require that a candidate for a university scholarship in some special subject such as history, classics or a science should attain a high standard in general subjects or even, as Sir Arthur Salter suggests, that any candidate for a degree should be required at some stage in his career to pass an examination in some aspect of the social sciences, might well be decisive. Merely to raise the age of the school-leaving examinations or matriculation so that they become, as they already are in Scotland, actual school-leaving examinations or entrance examinations to a university, might also assist to crush out the deplorable specialization of immature minds at school responsible for some of the most untoward results of the present system.

If, for these reasons, the initiative must largely lie with the universities, there are still other responsibilities in this field which they must accept. We are not concerned only with the students of the future or even with those at present

in residence. It is equally important to touch those who have completed their courses and now fill all types of posts in industry or the professions, in some of which they have already assumed responsibilities of leadership. Only as they are awakened to the opportunities which confront them and come to recognize the duties and responsibilities of citizenship can we hope to make democracy safe against its present dangers.

This, of course, is not a task for the universities alone. There is an ample field for the activities of the Association for Education in Citizenship; and the recent conference arranged by this Association at Ashridge on the "Challenge to Democracy" affords an admirable example of what is wanted. A panel of outstanding speakers was drawn from all shades of political opinion, and, excluding party politics, they discussed the clash of ideas between dictators and democrats from the point of view of believers in the ultimate value of the full and free development of each individual citizen. The first half of the programme was concerned with the essentials of democracy; the second with the formation of public opinion, including the schools, the universities, the Press and adult education. Such a conference can scarcely fail to have a powerful effect in stimulating clear thinking on everyday affairs, and the vision and moral determination essential as preludes to the action and perpetual vigilance in defence of democracy, which alone can preserve for us in these threatening days mankind's rich intellectual heritage and freedom of thought and speech.

An Inquiry into "Marvels"

A Book of Marvels

By Lieut.-Comdr. Rupert T. Gould. (The Fountain Library.) Pp. ix+180. (London: Methuen and Co., Ltd., 1937.) 2s. 6d. net.

THIS book is mainly a survey of records of certain phenomena occurring between 20 B.C. and A.D. 1890 which, after sifting and weighing the available evidence, the author deems worthy of the designation "marvels". Some, however, may think the book scarcely bears out its title; indeed, the author himself, in the majority of his collected cases, carefully refrains from divulging his own views—if any were held—concerning the

real significance of his "marvels". These may be summarized as follows:

(1) A line of foot-prints in the snow seen in Devon in 1855 which passed through—so it was said—locked gardens and over very high walls, haystacks, and roofs of houses, as though such things constituted no impedimenta. The impressions, which were in single file, were variously ascribed to a kangaroo, an otter, a badger, a donkey, a swan, and the Devil. Sir Richard Owen's opinion that the marks were made by a badger is discounted by Commander Gould on the score that, though Owen was an eminent palaeontologist, he was given to "making dogmatic assertions,

in defiance of fact, which proved him to be possessed of a singular and not entirely scientific type of mind". For example, he insisted that the hippocampus major is the exclusive prerogative of the human brain whereas, as proved by Sir W. Flower and Huxley, it is a structure man shares with the apes; moreover, did not Owen also—and this is where the gallant Commander's sea-boot pinches—in "his utterly childish 'explanation' of the sea-serpent seen by H.M.S. *Daedalus* in 1848" postulate that the naval officers who saw it "were, one and all, half-witted"!

(2) Movements, by unknown agents, of coffins in sealed-up vaults. Floods admittedly entered some of these vaults, robbers broke into others, while yet others were in an area of occasional seismic disturbances. In 1899 Alfred Russel Wallace quoted Dale Owen's account of the coffin movements at Arensburg as "the best evidence as to occurrences which were, and are, wholly inexplicable". The value of this particular evidence may be gauged from the fact that the account was given to Dale Owen in 1859 (fifteen years after the alleged movements) by people who had only troubled to visit the vaults some considerable time after they had heard that certain individuals reported "groans" coming from the cemetery. Commander Gould admits that the evidence in this case was at third hand, and even so by a person with very little capacity for assessing its value; yet in the same breath he maintains that in the case of certain other coffin movements the disturbing agent "was neither human nor natural".

(3) The next "marvel" is an alleged power to sense (*nauscopie*) the approach of ships far below the horizon—sometimes three or four days' run distant. As the principal 'wizard' in these feats attributed his successes—there were also misfires—to careful observations of high-level atmospheric changes induced by the presence of the vessels beneath, further comments are needless.

(4) We are then reminded of the giants with which hearsay has peopled the earth since the days of the tales of Titan and Typhon, but whose outward and visible signs have invariably turned out to be either the skeletal remains of mammoth or other large lower animals or, where actually seen in the flesh, victims of ill-balanced endocrine glands.

(5) Acoustic mysteries, such as the ringing of bells in houses by undiscovered agents, and the hammer-like sounds alleged to have been emitted by Memnon at Thebes and heard by various celebrities between 20 B.C. and A.D. 190, since which date there has been silence. In the author's opinion, unequal expansion of the materials of the Colossus was the probable cause of the sounds.

(6) The most interesting part of the book is undoubtedly the account of some experiments carried out by Captain W. E. Parry in 1822 to determine the velocity of sound. At Winter's Island, with thermometer showing -25°F. , and the barometer 28.84 inches, fifteen rounds were fired from a six-pounder gun at an angle of elevation of 10° , the times of flash and report being recorded by observers 5,645 ft. distant. The mean of these gave a velocity of 1,023 ft. per sec. What perplexed Parry, however, was that the order 'Fire!' sometimes reached the observer about half a second *after* the gun's report. Commander Gould endorses an explanation of this anomaly which was sent him by a correspondent, namely, that as the velocity of sound increases with increase of temperature, the word 'Fire!', travelling over a slightly colder route nearer the ice, reached the observers after the report of the gun which, in consequence of the 10° elevation, passed through a higher and slightly warmer air route. This explanation, in view of what must have been a very slight difference of temperature (t) of the two converging sound paths, seems to the reviewer far-fetched, especially in the light of the formula $v=1093\sqrt{1+0.00366\ t}$. It has been shown by many experiments that the velocity of the compression wave of sound increases with its intensity, a violent noise actually travelling faster than a gentle one. Jacques, for example, found that the sound emitted by the explosion of half a pound of gunpowder travelled at 1,032 ft. per sec., while that from $1\frac{1}{2}$ pounds had a velocity of 1,187 ft. per sec. Surely this principle better explains the anomaly referred to by Gould. Other acoustic mysteries alluded to are distant cannon-like rumblings occasionally heard in mountainous regions. Colonel Godwin Austen, whose name is immortalized in the 28,265 feet high Himalayan peak, heard them when surveying in 1865. Similar sounds are also heard off the Belgian coast where, says Gould, they are locally known as 'fog-hiccups'.

The book concludes with *pro* and *con* arguments concerning the presence of canals in Mars.

These chapters, which must have involved a considerable amount of diligent delving into ancient records, savour in the majority of cases of much ado about nothing. We are surrounded by marvels; they make contact with us every day of our lives. How do radiation waves, from the fifteen-mile-long Hertizian, to the twenty million millionth of an inch cosmic waves, make their way through a *vacuum*? What is the secret of 'action at a distance', and how does an apple fall to the ground? What are 'energy' and 'matter', how are they mutually convertible, and how does the brain, as a synthesized aggregation

of their fundamentals—photons, electrons and protons—feel, think, and—marvel? Here, indeed, are matters worthy of wonder, real marvels which put the mysterious pullings of bell-wires and movements of coffins in their proper perspective. Hearsay statements concerning events the causes of which were not ascertained, especially when made by credulous people with a mystical bent,

though not necessarily devoid of truth, are always suspect. Science has carried all before it in virtue of two golden rules, the one, to “take no man’s word for it”, the other to be economical in assumptions in accordance with the Law of Parsimony that causes are not to be multiplied beyond mental necessity—*Entia non sunt multiplicanda praeter necessitatem*.
CHARLES M. BRADNELL.

A Compilation on Migrations

The Wandering Spirit:

a Study of Human Migration. By Dr. Ragnar Numelin. Pp. xvi+375. (London: Macmillan and Co., Ltd., 1937.) 20s. net.

IN his attempt to analyse the conditions and stimuli underlying human migrations, Dr. Numelin has cast his net over the entire world, and has considered human movements from Palaeolithic times down to the present day. But, although his many citations show that the physical and social conditions promoting migration are very complex, his methods and criteria are too vague to yield satisfactory results.

Despite his strictures on their loose use by others, the author uses terms like migration, wandering and nomadism without clear distinction, and he often fails to discriminate between seasonal movements of all or part of a community within its territory and group migration from one territory to another. Much of the movement among food-gathering peoples, of which he cites many examples, is in its seasonal and cyclic character to be distinguished clearly from large-scale displacements under pressure of food shortage or human enemies, and the author does not seem to have considered the evidence for territorial fixation among these peoples. This confusion of seasonal movements and journeying with migration in the sense of permanent displacement also leads him to regard fishing peoples as more migratory than primitive collecting and hunting groups. There is much evidence from western North America and north-eastern Asia, not mentioned by Dr. Numelin, which suggests that the contrary is more generally true.

Although a great deal of material is brought together in this volume, the use of sources is often very uncritical. The author frequently omits to mention or consider much recent work on peoples discussed, while general statements and assumptions of earlier writers are accepted as definitive. Assuming that remote linguistic relationships imply tribal migration between particular areas,

he reaches improbable conclusions which are supported by no real evidence. The Iroquois, for example, are described as having migrated as coherent tribal groups from country west of the Mississippi, and the Navajo are brought to New Mexico from Alaska!

Dr. Numelin accepts creation myths as evidence of the origin and course of migrations of particular peoples, citing with approval for the Pueblo area the conclusions of Fewkes which, as later workers have shown, reduced the theory of historical migrations to absurdity. On the other hand, he does not refer to the more recent studies of Pueblo society by Kroeber, Parsons, and others, in which observed processes of fission and migration have been analysed. He gives numerous references to pilgrimages, trade journeys, and shifting of house and village site after death or pestilence, but does not discuss either the cumulative effects of such practices or their relation to group migration.

Although the discussion of “subsistence—geographical” conditions of migration, that is, the relation between the economy and the physical conditions at a particular place and time, is in general more satisfactory, and there are useful summaries of material on transhumance and other forms of seasonal migration in Europe, the evaluation of social and physiographical factors is rarely adequate. The author occasionally lapses into crude determinism. He refers frequently to mental qualities and uses the misleading term ‘instinct’, but does not present either a clear statement or cogent evidence concerning the part played by psychological factors.

This laborious piece of work has unfortunately been undertaken without either a clear formulation of the problems to be investigated or an adequate knowledge of recent methods and results in social anthropology. Dr. Numelin has not been very happily guided by those who revised his English text, for the writing is often unidiomatic, and his meaning is sometimes quite obscure.

Académie des Sciences de l'URSS, 1936 and
1937.) 32+17 roubles.

THE Mendeléeff centenary congress held in Leningrad during September 1934 was described directly afterwards in *NATURE* (134, 799; 1934). The official report has just appeared.

The first volume contains the speeches of the Russian organizers and foreign guests, and all the lectures delivered in Leningrad. It is obviously intended for readers both in Russia and abroad; all the official Russian speeches are here followed by French versions, Russian lectures by translations into French or German, while lectures given in either of these languages—English was not used at the congress—are rendered into Russian also. There is no need to give a list of the speakers and their subjects, as these are already mentioned in the article in *NATURE* referred to above. Those lectures dealing with modern scientific questions have lost something of their topical interest through the long delay, though the various historical contributions are scarcely affected by the two years' procrastination.

Most of the foreign delegates to the congress were unable to follow the Russian speeches. While probably they were all impressed by the picturesque welcome offered by the delegation of Moscow chemical workmen, only now can they realize that the address spoken by their representative was one of the most significant delivered at the opening meeting, giving an account of the development of the Russian chemical industry; and that Prof. Nametkin's lecture traces in a most interesting manner Mendeléeff's endeavour to promote the petroleum industry in Russia. Those of Mendeléeff's admirers who had so far venerated him only as an investigator will be glad to learn how energetically he used his influence to direct this industry in the way he thought best for the benefit of his country.

The lectures delivered during the less formal continuation of the celebrations in Moscow; a few more already held in February 1934 at a meeting of the Russian Academy; and several papers which were only presented in manuscript and not read, form the subject of the second volume. The contributions by the Russian men of science frequently throw illuminating side-lights on Mendeléeff's rich and unconventional

personality; Prof. S. I. Vavilov, in a paper on the importance of physics in Mendeléeff's scientific activities, incidentally mentions that his various interests, and their simultaneity, are reflected in his private library: it contains many books, bound by himself, which unite in the same volume novels with chemical and mathematical papers.

Some of the authors have taken the opportunity of extending their addresses. Prof. Wilh. Palmaer (Stockholm) presents in no less than fifty pages a survey of his own and his co-workers researches on the corrosion of metals; two excellent plates in colour illustrate his descriptions. In a few other cases one may be inclined to regret that the authors have strictly confined themselves to their spoken addresses; if, for example, Prof. W. Noddack (Freiburg) in his remarks on the Periodic System criticizes the evidence brought forward by some investigators for the existence of the elements 61, 85 and 87, readers may ask whether the proof which he himself offered so early as 1925 for the discovery of element 43 (masurium) is any more valid; as no confirmation has been forthcoming, it might be advisable to extend his well-founded scepticism also to this place of the Periodic System.

The delay in publication is probably due to an endeavour to produce a technically faultless book, and it must be acknowledged that the two stately volumes show none of those shortcomings in paper or print so frequently met with in Russian publications. This excellent typographic achievement and the great care devoted to the German and French texts and translations deserve high praise; although they may not always be linguistically quite correct, it is very remarkable that the Russian printers and proof-readers are able to produce such long and difficult treatises practically free from misprints in foreign languages.

At the end of the second part the names of the ten honorary presidents—the list being headed by J. V. Stalin—34 presidents, 34 members of the Organizing Committee, 28 foreign and 253 Soviet delegates, and additional official details are given. Many good reproductions of pictures adorn the volumes, amongst them portraits of Mendeléeff's father and mother, which are probably little known outside Russia.

The efforts made in 1934 by the Russian authorities and scientific workers to celebrate one of their greatest compatriots are now put on record in an appropriate manner by these two fine volumes.

F. A. P.

The Plant Diseases of Great Britain :

a Bibliography. Compiled and annotated by Dr. G. C. Ainsworth. Pp. xii+273. (London : Chapman and Hall, Ltd., 1937.) 15s. net.

THIS book, to which Dr. E. J. Butler has contributed a foreword, is a successful attempt to provide the plant pathologist—at rather a high price—with the key references to the literature on the principal plant diseases of Great Britain. The 183 host plants are conveniently arranged in groups as in the Ministry of Agriculture's reports on the annual occurrence of plant diseases, from which most of the nine hundred diseases included were taken. Under each host there is a list of diseases that may affect the plant and, where possible, the common names applied to these diseases are those recommended by the Plant Pathology Committee of the British Mycological Society. The attempt to name viruses and virus diseases will be particularly welcomed by plant pathologists. A selected list of literature references, mainly English but with a sprinkling of foreign papers, is given for the majority of the diseases, and each reference is briefly annotated to indicate the contents of the paper. Where a paper is abstracted in the *Review of Applied Mycology* a reference to this is given. Two indexes are provided, one of authors and one of hosts and parasites.

The selection of the English literature has been extremely well made, but many quite uncommon or doubtfully parasitic diseases are included without comment. Indeed, the value of the book to economic workers, both in Great Britain and Overseas, would have been greatly increased if the author had attempted to assess the relative importance of the diseases, for the number of articles published about a particular disease is apt to give a very misleading impression of its economic significance. The references have evidently been carefully checked, but elsewhere misprints are frequent.

W. C. M.

Commercial A.C. Measurements

By G. W. Stubbings. Second edition, revised. Pp. xvi+348. (London : Chapman and Hall, Ltd., 1937.) 15s. net.

THIS book has been written primarily for testing engineers. For students reading for engineering examinations it will not be so useful, as there are no examples given to illustrate the application of the theory given to practical work. The author has reduced the mathematical theory to a minimum, and so does not discuss the cases where three vectors cannot be represented by three lines lying in one plane, or stated the full conditions that must be satisfied in order that the power factor of a circuit may be unity.

The author's descriptions are easy to follow and he is thoroughly familiar with the methods used in the testing departments of power stations. Apparently it is customary to express the errors of watt-hour meters as a percentage of the true registration, the number being + (positive) if the meter is fast and - (negative) if it is slow. The average consumer would probably understand the meter card more easily if fast were written for + and slow for -. It is quite unnecessary to burden the memory in this case.

Handbook of Engineering Fundamentals

Prepared by a Staff of Specialists under the Editorship of Ovid W. Eshbach. (Wiley Engineering Handbook Series, Vol. 1.) Pp. xii+1036+50. (New York : John Wiley and Sons, Inc. ; London : Chapman and Hall, Ltd., 1936.) 25s. net.

THIS book is divided into thirteen sections beginning with mathematical and physical tables and proceeding through such other subjects as mathematics, mechanics, flow of fluids, thermodynamics, electricity and magnetism, radiation, light, acoustics and meteorology, chemistry, metallic and non-metallic materials, to a final section on contracts, and certainly deals with the fundamental subjects required by the engineer.

The forty authors responsible for this work have been selected in equal numbers from the academic and industrial fields, so that, whilst the theoretical aspects of the various subjects are not overlooked, the practical applications of the theories receive due attention.

Intended as an introduction to the two volumes comprising Kent's "Engineering Handbook", and the two volumes constituting the "Handbook for Electrical Engineers", all of which are of uniform size, it possesses much useful information, but the English reader must always remember that it treats of American practice. Although containing nearly eleven hundred pages, the book is of convenient size, clearly printed, well illustrated, and firmly bound in flexible covers ; it should prove a useful addition to the library of the engineer.

The Metabolism of Living Tissues

By Dr. Eric Holmes. Pp. xi+235. (Cambridge : At the University Press, 1937.) 7s. 6d. net.

SIR F. GOWLAND HOPKINS has written a foreword in which he calls this a highly original book. Its chief claim to originality probably lies in its popular style, which strays from the narrow vocabulary generally used in scientific works in a way that is likely to shock the purists. The book is meant to be read straight through by students of biochemistry at the beginning of their course, and is likely to appeal to such readers. Advantage has been taken of the fact that the contemplation of structural formulae brings aesthetic satisfaction to many who do not really understand them. Such contemplation is encouraged by an invitation to compare the formula of the lactoflavin in vitamin B₂ with the prosthetic group of Warburg's yellow pigment. The two substances are identical, but it takes the beginner some time to discover this fact because the two versions of the formula are written differently.

After some general remarks about enzymes, oxidations and redox potentials, the metabolism of the liver, kidney, muscles and nervous system are discussed in separate chapters, with particular emphasis on carbohydrate metabolism. This is probably the best part of the book. Hormones and vitamins are mentioned in later chapters, and their formulae given. The book is intended as an introduction. There is a danger that it will come to be regarded by students as a complete account of all that they need to know.

Chemistry of Indian Opium

By Dr. H. B. Dunncliff, Chemical Adviser, Central Board of Revenue,
Government of India

OPPIUM is the spontaneously coagulated latex which exudes when the partly ripened capsules of *Papaver somniferum* L. are lanced on the living plant. On exposure to air, the white, pale-yellow or pink latex turns darkish brown and, increasing progressively in viscosity, finally becomes quite hard. The product, called 'raw opium', is brown and soft inside, and has a characteristic smell and bitter taste. As marketed, raw opium contains about 15 per cent of water, some sugar, salts, albuminous substances and colouring matter. Its most valuable constituents are varying amounts of the meconates of some twenty-five alkaloids, the chief of which is morphine. At the time of collection, the content of morphine in Indian opium is not less than 8 per cent, though 16-20 per cent has been recorded when only latex from first lancements were taken. Narcotine (5-7 per cent); codeine (1-2 per cent), papaverine (0.4-1 per cent), thebaine (0.2-0.5 per cent) and narceine (0.5-1 per cent) are also present.

Opium waste products and contraband opium are used for the manufacture of morphine and other opium alkaloids. Excise opium is used in medicine, but in India much is chewed in harmless quantities.

The Hague Convention and the Dangerous Drugs Convention of 1925 have given international definitions to the two other varieties of the commercial drug, "prepared opium" and "medicinal opium". For the latter, selected chalans of raw opium containing 9.5-10.5 per cent of morphine are employed.

In 1926, the Government of India discontinued the auctioning of "provision" opium for export and undertook the sales direct, the policy for many years having been to deal only with Governments. Also the supplies to Far Eastern countries for purposes other than medical and scientific were reduced by 10 per cent annually so as to extinguish exports by December 1935. This decision has involved great financial sacrifice to India, the sales in 1926-27 having yielded 3.36 crores of rupees (a crore is ten million rupees, approximately £750,000), while, in 1936-37, no revenue was collected under this head.

Experts have been frequently employed to report on the preparation of standard opium for sale and, for nearly thirty years, the technical side of the factory has been under the control of a chemist. W. A. Davis, indigo research chemist

to the Government of India, deputed to report on the manufacture of medical opium and opium alkaloids at Ghazipur, recommended the installation of modern factory and laboratory research equipment, and showed how the Ghazipur Factory could produce a standard opium in sufficient quantity completely to replace that from Turkey and Persia in the English and American markets. Indian medical opium, the manufacture of which at Ghazipur was first undertaken during the Great War to replace the supplies no longer available from Turkey owing to international hostilities, is a better standardized product than that from Turkey. Indian opium also contains more codeine (2-4 per cent) than the Turkish variety (less than 1 per cent).

H. E. Annett and his co-workers* have made valuable contributions to the chemistry of opium and its alkaloids. With Bose, he showed that the observed increase in the percentage ash of the latex of the opium poppy at each successive lancing up to the fourth is accompanied by a decrease in the total alkaloid content of the latex. The principal loss was in morphine, while the codeine-morphine ratio rapidly increased at successive lancements. They failed to establish any relationship between the nature of the soil and the morphine content of the opium grown on it, though there was clearly some local factor influencing the power of a plant to produce the alkaloids. Different races of poppy possibly produced opium of varying morphine content and special strains could be produced by selective manuring. Organic manures caused an increased yield of opium of higher morphine content. Similar results with superphosphate linked the beneficial effect with the phosphoric acid in the manure.

Indian opium was, and still is, inferior to Turkish opium in morphine content. This can be ascribed to such factors as faulty methods of harvesting, defective lancing and collecting, the deterioration of opium on storage and environmental conditions in India, which are unfavourable when compared with those of Turkey, where the latex is collected in a moist atmosphere with a falling temperature, while the reverse conditions, favourable to bacterial deterioration, prevail in India.

In cloudy or moist weather a brown, watery substance called 'pasewa' exudes from opium. It used to be employed as 'lewa', a mixture of pasewa and inferior opium, in pasting poppy petals as a protective layer round the balls of provision

opium. Opium mixed with excess of pasewa is termed 'pasewa amez', but little is known of the genesis, chemistry or properties of pasewa and its peculiar sensitiveness to climatic conditions.

Considerable controversy arose over the assays of opium and its alkaloids submitted to the English market for sale. These differences between results of the English chemists and the Indian factory analysis were traced to different methods being employed for the evaluation of the opium and the purity of morphine hydrochloride, and the interpretation of the results.

In 1915, the chemical work of the Ghazipur Laboratory was done by the assistant opium examiner, W. W. Todrick. His staff was augmented in 1915 by a chemical assistant, J. N. Rakshit (Rai Sahib, 1926), who eventually succeeded Todrick. Later he was designated factory chemist, but in 1929 he was appointed to the newly created post of opium chemist to the Government of India.

In 1917, Rakshit¹ showed that opium yields about 2.5 per cent ammonia, and, a year later, isolated a complex substance he called "opium wax"². Its composition varies widely from different sources, giving saponification values, 113-126, acid values, 41-45, and iodine values 130-170. The presence of hydrocarbons is also indicated, and from two other components; J. N. Ray (Lahore, unpublished work) has separated acids melting at 76° and 178° respectively, the latter being most probably a resin acid. Hence Ray suggests that opium wax is probably a resin, since destructive distillation yields an oily product resembling the higher terpenes.

Rakshit³ isolated porphyroxine from opium and reported it to be a crystalline compound with a sharp melting point different from the mixtures examined by Merck (1837), Dey (1883) and Hesse (1894). Rakshit's proposed structure for this compound has been the subject of criticism in view of the development of the chemistry of morphine.

The determination of the morphine content is a most important but controversial question, leading to modifications of standard procedure from time to time.

The Indian Opium Factory sales of medical opium of standard strength for supply to medical men and hospitals have increased from 511 lb. in 1922 to 1,800 lb. of medical opium powder and medical opium cake of B.P. 1932 strength in 1936. During the year ending September 30, 1936, 1578 lb. of crude morphine, 130 lb. of morphine hydrochloride, 14 lb. of morphine sulphate and 284 lb. of codeine were sold from the Factory. Cotarnine prepared by the oxidation of narcotine has been made to supply special orders.

Literature on the problem of the loss of morphine from opium on storage has been summarized

in an article by Dunncliff, Ray and Singh⁴. Their investigations show that the morphine content of Indian opium does not fall if it is stored under anaerobic conditions in a moist condition but that, if dried at 60° and stored in contact with air, it suffers a rapid loss of the alkaloid. When dried at 98°-100° and stored out of contact with air, the fall in morphine content is small. Simple trituration of opium with lime shows that there are ammonium salts present, but it is claimed that their formation is not due to the degradation of morphine as hitherto believed.

The consumption of excise opium in India has decreased steadily for the last six or seven years, the issues from the Ghazipur Factory having fallen from 12,767 maunds in 1919 to 5,665 maunds in 1936. This decline is to be attributed partly to the economic depression of recent years and partly to the steady increase in the duty on opium. To a large extent, opium-eating in India is quasi-medical, being used by the poor as a very common and highly valued household remedy. Its physiological importance depends not only on its morphine content but also on the presence of alkaloids like codeine, papaverine, etc., which assist in the relief of many ailments.

The conclusion that opium may have an anti-malarial action was based on the low incidence of malaria in certain districts where opium was regularly consumed. Gordon affirmed the prophylactic value of narcotine against malaria, but Chopra and Knowles⁵ have shown that it has neither curative nor prophylactic value in malaria, even in large doses.

Ahluwalia, Kochhar and Ray⁶ oxidized narcotine to cotarnine in good yield and prepared a number of derivatives of cotarnine. One of these formed from resorcinol was found, like quinine, to be an antipyretic and toxic to *Paramecia*. Its acetyl derivative may possibly find some application in gynaecology, while cotarnine phthalate is a stypic.

The opium habit, the physiological results of smoking opium, the effect of opium and morphine on the human system and morphine addiction in India have all received the attention of scientific workers and official commissions⁷, from the reports of which valuable information on these important sociological problems may be found.

Recent Caterpillar Plagues in Great Britain

THE epidemic occurrence of the caterpillars of the Antler moth (*Charaxes graminis* L.) in the north of England and Scotland, and of the Willow 'Small Ermine' moth (*Hypnomena rorella* Hb.) in Suffolk, have been the subject of considerable comment, not to say confusion, in the daily Press, and since the two outbreaks are of a very different type a brief account of their essential features may be of interest.

The species first mentioned is widely distributed throughout Great Britain, haunting chiefly moor or downland, and the poorer types of pasture, where the larvæ feed on *Festuca ovina*, *Nardus stricta*, and grasses of a similar type. In lowland regions, the Antler moth appears never to increase to such numbers as to do appreciable harm; but in hill districts from South Wales and Derbyshire northwards, moorland pastures, usually at a considerable elevation, may suffer very severely, the grasses being largely destroyed and only a brown 'mat' of dead grass left. The caterpillars then occur in such numbers as to be driven by starvation to migrate in vast hordes, blocking streams and water courses, or collecting in heaps at the base of walls or other obstacles. This migratory stage, if that term be applicable, is reached when the caterpillars have nearly completed their feeding, and although a certain proportion crawl downhill towards the lowland meadows, the latter never seem to be damaged. Antler moth outbreaks occur relatively infrequently, as the following records show, although there may have been others on a smaller scale of which records have been overlooked, notably between 1827 and 1881:

- 1827 Skiddaw¹.
- 1881 Lancashire (Clitheroe)², Derbyshire³.
- 1884 Glamorgan⁴.
- 1885 Selkirk⁵.
- 1894-95 Selkirk and south-west Scotland⁶.
- 1910 Glamorgan⁷.
- 1917 Derbyshire⁸.
- 1935 Wales (Brecon).
- 1936 Brecon Beacons and Cader Idris, north-west England.
- 1937 Cader Idris (slight compared with 1936), north-west England, Scotland.

It is evident, therefore, that outbreaks seldom occur for more than two years in succession in the same area, and often they are confined to single years with long intervals in between. The factors

that lead to these enormous increases in numbers are at present unknown. The outbreak in Derbyshire in 1917 was investigated by Imms and Cole⁹, and they suggested that these factors were possibly climatic, and the fact that the hills were snow-covered in 1916-17 might have given the species greater protection during that winter. Since, however, the insect spends this season in the egg stage (a fact not then known) this explanation is not very likely to be correct. An alternative suggestion discussed by Imms and Cole was that the failure to burn hill pastures during the Great War had favoured the outbreak, but again this explanation can scarcely apply generally, and it is more probable that the causes of an outbreak are complex and due to the interaction of both climatic factors and the varying incidence of the natural enemies of the moth.

The matter clearly needs investigation; but owing to the considerable period of years that may elapse between outbreaks and the necessity for intensive field and laboratory work every year, regardless of outbreaks, the problem would seem to be more appropriate to a university department with a succession of students than to a research worker in economic entomology, who would not be able to give annually so large an amount of time required to a problem that, taken over an average of years, is not of great economic importance. So far as direct control measures are concerned, nothing of a practical nature is yet known, since the value per acre of moorland grazing is so small that it will not carry any appreciable expenditure on caterpillar control.

The Antler moth outbreaks are thus typical of a resident species that normally occurs in small numbers, but is occasionally released from the factors that exercise a natural control.

The outbreak of the other species attracting attention, the Willow Small Ermine moth (*Hypnomena rorella*) is of a different character. This moth, until 1936, was regarded as a very rare species in Great Britain, having been noted only in Sussex and Dorset, and even in these counties there seems to be no record of any permanent colony. In 1936, however, the marshland willow trees in the neighbourhood of Beccles in Suffolk were found to be heavily infested by the larvæ, and specimens were also received from Barnby, farther down the Waveney valley, while a single specimen was taken at Rockland Broad in the valley of the Yare in Norfolk, some twelve miles from Beccles⁷.

According to Goldsmith, who first recorded the Suffolk outbreak*, larvæ had been noted at Beccles some five years before his attention was directed to them. It is thus possible that there may have been a small nuclear colony of the species in Suffolk for many years. This, however, is not very likely, since the Beccles neighbourhood has been fairly well worked in respect of the Lepidoptera, and the 'nests' of the larvæ are so conspicuous that they could scarcely be overlooked. On the whole, it is more probable that the species is a recent arrival in Suffolk, having either flown or been carried by boat from the Continent.

If this suggestion is correct, the conditions favouring an epidemic increase might easily have been fulfilled, since the moth would arrive without its natural parasites, and feeding upon willows in a marshland district, where other members of the genus are not abundant, it would gain some years' start before being found by any indigenous parasites. In 1936, the rate of parasitism was certainly very low. Mr. Stringer, of the British Museum (Natural History), reared from Beccles larvæ the species *Herpestomus brunneicornis* Grav., an ichneumonid that frequently attacks the allied *Hyponomeuta padella*; but the writer obtained no parasites whatever either from Beccles or from Barnby material.

Provisionally, then, *H. rorella* may be regarded as an invader (in contradistinction to the indigenous *C. graminis*), and although it is very unsafe to prophesy, it is at least possible that it will be increasingly parasitized, and even perhaps brought completely under control as soon as it is discovered

by the parasites of our native species of *Hyponomeuta*—a process that might be hastened artificially if it were considered worth while.

As to the economic importance of the insect, it is not possible as yet to give any definite opinion. If cricket bat willow or basket willow were attacked, the species might prove a serious menace, notably to the former, since the spraying of large trees is seldom commercially worth while. Fortunately, there is some hope that neither will be affected. In Suffolk, the trees that are suffering appear to be *Salix alba* (although the writer claims no expert knowledge in this respect). However this may be, larvæ of the *rorella* brought from Beccles, and also others reared in captivity from the egg, have been given the foliage of the true cricket bat willow, but neither in 1936 nor 1937 were they able to survive on it. Similarly, they refused to feed on *Salix caprea* or other 'sallows', or on one of the basket willows that was given them. The experiments were not sufficiently extensive to justify any final conclusion in respect of the cricket bat willow, but they are at least suggestive and show that *H. rorella* is very specific in its tastes.

A note on the outbreak in 1936 was published in the *Entomologist*, to which readers may be referred for a description of the larvæ and the damage they do. J. C. F. F.

Nottingham Meeting of the British Association

AS has already been announced, the annual meeting of the British Association will this year be held in Nottingham on September 1-8, under the presidency of Sir Edward Poulton. Twice previously the Association has held its annual meeting in Nottingham. In 1866, before the foundation of University College, Nottingham, Mr. Justice Grove, Q.C., the inventor of the Grove cell, was president. It was at this meeting that Wheatstone was president of Section A (Mathematics and Physics), before which Joule read a short paper on the heating effect of an electric current in a wire, and one wonders if this paper was an abridged version of that which Wheatstone is reputed to have rejected in his capacity as a referee for Royal Society publications. At the same meeting, Sir William Huggins gave an evening

discourse on the applications of spectroscopy to the problems of stellar constitution. Among the more distinguished members present in 1866 were Frank Buckland, T. H. Huxley, A. R. Wallace, W. Crookes and H. E. Roscoe, while Dean Farrar contributed to discussions on the teaching of science in public schools, and C. F. Varley reported on the Atlantic cable successfully completed a month before the meeting. Among the visits paid to local industrial undertakings was one to Messrs. Taylor's bell foundry in Loughborough, and it is pleasant to think that members will again have an opportunity of visiting the works this September.

In 1881 the University College, Nottingham, buildings in Shakespeare Street, near the centre of the city, were opened, and these were the headquarters of the Association at its annual meeting

in 1893. Dr. J. S. Burdon Sanderson was president, and Sir Richard Glazebrook was president of Section A, which was remarkably active, and at which a committee presented a report on the foundation of a National Physical Laboratory.

This year the Association will hold all its sectional meetings in the University College buildings in University Park, provided by the munificence of the late Lord Trent and opened by H.M. King George V in July 1928. Here the members will be able to enjoy extremely pleasant surroundings, and, if they wish, refresh themselves in an open-air swimming pool.

Nottingham is the centre of a large number of industries; its connexion with textiles is well known, and there are large chemical, mining, tobacco, bicycle and general engineering undertakings in the city and immediate vicinity. Since the last meeting here, interest in lace manufacture has declined, or, rather, been replaced by activity in hosiery manufacture. Visits to representative works have been arranged, including an excursion to a coal mine, and the Geography and Geology Sections of the Association are combining in a discussion on the potential resources of the area. Members visiting Nottingham for the first time will find much to interest them in the many excursions which have been arranged to the surrounding countryside.

A meeting in which local members should be considerably interested is an evening discussion

arranged between six sections on the planning of the land of Britain. A joint meeting of the Education and Geology Sections to discuss the teaching of geology in schools is also likely to be keenly followed, and Mr. H. G. Wells's presidential address to the Education Section will naturally be of considerable interest. In addition to the evening discourses, one on "Illusions of Colour" to be given by Prof. H. Hartridge and another on "Grass and the National Food Supply" by Dr. R. E. Slade, a series of popular lectures for non-members has been arranged in the neighbouring towns. Dr. Alexander Wood will address a company of Nottingham children on "Noise", Sir Gilbert Walker will talk to a Derby audience on "The Science of Sports", Mr. R. Kay Gresswell will talk on "Rivers" at Lincoln, Dr. J. E. Constable on "Everyday Application of Physics" at Long Eaton, Prof. J. Walton on "Coal and its Origin" at Mansfield and Mr. T. M. Herbert on "Transport of Food" at Newark.

The Lord Mayor and members of the City Council will hold a civic reception at Nottingham Castle on Thursday evening, September 2, and the College Council will give a garden party on September 7. On these occasions members should find ample opportunity of meeting many of the local scientific workers and citizens who are interested in the aims and objects of the Association and who are working to make the Nottingham meeting a successful one in every way.

Obituary Notices

Prof. Thomas Mather, F.R.S.

THOMAS MATHER was a man who worked his way up to an important and honourable position from a starting condition devoid of all advantages due to financial or personal support. His early training was that of a carpenter. By strenuous evening study he won a Whitworth Scholarship at a time when these scholarships were few in number and of greater money value than is nowadays the case. With the aid of this scholarship, he supported himself at college throughout a fairly complete course of full-time study. His early education was not such as to make it possible for him to meet all the academic conditions at that time needed in order to qualify for a science degree. He could not get a degree but he could, and did, work hard at physical, mathematical, and engineering subjects, so as to leave college with a thorough grip of them. He next became an assistant to Prof. W. E. Ayrton at the start of the technical teaching work financed by the City and Guilds of London Institute. He followed Prof. Ayrton from the college at Finsbury to the one at South Kensington

which is now part of the Imperial College. On the death of Prof. Ayrton he succeeded him as professor of electrical engineering. When he died on June 23, he had lived more than eighty-one years, and during half that period he was a fellow of the Royal Society.

Mather joined Prof. Ayrton's staff at Finsbury in 1881 before the College was actually built, and while the City-Guilds classes were carried on in a boys' school, part of the playground of which was afterwards used as the site for the College. The classes at the school and later on at the College were held mainly in the evening, and were thronged with adult students all engaged in the new industry of electrical engineering. At that time, trained men were not to be found, and electrical engineering departments did not exist. There was a new and sudden demand for large laboratory classes to train men in the use of apparatus utilizing electrical currents of a magnitude previously unknown. The development of suitable training courses with corresponding testing appliances called for much ability and initiative. Prof. Ayrton

at first directed this work, but later on was content to leave it almost entirely in the capable hands of his assistant. The work grew in volume and altered in character with the change from the Finsbury to the South Kensington College, with the establishment of three-year College day-courses, and with the rapid development of electrical engineering. As years passed, the laboratories had to be enlarged and their equipment increased, and many new members of the staff had to be engaged. Mather throughout remained in control. The main work of Mather's life consisted in the development of these laboratories and in the constant assistance given by him to those who worked in them whether as ordinary course students or as exceptional ones, like Duddell, carrying out important original work.

For many years, Mather could not lecture since his speaking suffered from an impediment so serious that he often had to resort to paper to explain what he wished to say. He was quite unable to take part in the discussions at the Institution of Electrical Engineers, or at the Physical Society. Had he been able to do so, he would have been more adequately appreciated outside the College than was the case. His struggles to overcome his disability were at times pathetic, but during and after 1914, to the astonishment and delight of everyone who knew him, he was able to give lectures. These were highly esteemed by his students.

From the pure science point of view, Mather's most valuable work was an investigation concerning details in the improvement of the standard cell and involving an accurate determination of its electromotive force. This work formed the subject of papers to the Royal Society, and was probably the main factor determining his election to the fellowship of the Society.

Technical men will remember Mather best for a number of papers written, mostly in conjunction with Prof. Ayton, dealing with improvements in the construction of electrical instruments of all kinds. An instance is a set of papers on galvanometers and accessories such as the well-known Ayton-Mather shunt. Another consists of his work on electrostatic voltmeters, which involved most skilful and careful design. These instruments were widely used in practice, since at the time they were first produced they were much wanted and were the best available instruments of their kind. The precision wattmeter of Mather and Duddell is another instance of the excellence and care in detail of Mather's work. First-rate instruments and appliances suitable for college or industrial testing are now commonplace articles of commerce, but such a result could only be reached after much previous work had been done in laboratories established for technical teaching. Mather was one of the earliest and ablest pioneers in this work.

In nature, Prof. Mather was most modest and retiring. He was always kindly and willing to help in either simple or advanced work, and never wished to have such help acknowledged in public. He was

personally much liked and was held in honour by all who knew him. It would be hard to value too highly the influence of a man who spent so many years guiding the laboratory training of ordinary students and in helping in the research work of others, many of whom have become highly distinguished men.

Prof. Albert Griffiths

PROF. ALBERT GRIFFITHS was born at Chester on October 8, 1867, and after the removal of his family to Manchester was educated at the Manchester Central School, the Royal College of Science, London, and in 1887 won the Dalton entrance scholarship to the Owens College, Manchester, then one of the constituent colleges of the Victoria University. He was one of the first students to read for the honours degree in physics of the University, and at the end of his first year was awarded the Heginbottom Scholarship. He obtained the degree of B.Sc. with first-class honours in 1890, and went to Germany to continue his studies at Freiburg.

In 1893 Griffiths was elected to a Bishop Berkeley fellowship at the Owens College, and commenced a series of electrical researches, an account of which he published in the *Philosophical Magazine*, vol. 39, in 1895. He was appointed demonstrator in physics on the termination of his fellowship in 1895 and lecturer in physics at University College, Sheffield, in 1898.

Griffiths obtained his D.Sc. degree in 1899 and in the following year, after acting as head of one of the students' hostels at Sheffield, was appointed head of the physics department of Birkbeck College, London, and ultimately professor of physics. He held this position until his retirement in 1933, and founded a school of research which concerned itself mainly with problems of diffusion of salts in solutions and improvements in the methods of determining coefficients of diffusion. Heart trouble set in during the summer of 1935 and became rapidly worse early in 1937; he died on May 24. He leaves a widow and one son.

We regret to announce the following deaths:

Prof. H. E. Armstrong, F.R.S., emeritus professor of chemistry in the Imperial College of Science and Technology, City and Guilds (Engineering) College, on July 13, aged eighty-nine years.

Dr. A. A. Bialynski-Birula, formerly director of the Zoological Museum of the Russian Academy of Sciences, known for his zoological work in the Arctic and for systematic work on scorpions and Solifugidae, aged seventy-three years.

The Right Hon. Lord Ernle, M.V.O., president of the Board of Agriculture and Fisheries in 1916-19, who received the Gold Medal for 1935 of the Royal Agricultural Society "for distinguished service to the farming industry", on July 1, aged eighty-five years.

Prof. A. W. Gibb, emeritus professor of geology in the University of Aberdeen, on July 12, aged seventy-three years.

News and Views

H.M. the Queen and the University of Edinburgh.

At a special graduation ceremonial on July 8, the *Senatus Academicus* of the University of Edinburgh conferred on Her Majesty the Queen the honorary degree of doctor of laws. The degree was conferred by the vice-chancellor, Sir Thomas Holland, who expressed to Her Majesty the thanks of the University. In her reply, Her Majesty said, "I thank you, Mr. Vice-Chancellor, for the very kind words with which you have admitted me to-day to your Roll of Honour, and I assure you that I deeply appreciate the distinction which the University of Edinburgh has conferred upon me. As a Scotswoman I know the high value which my fellow-countrymen set upon education, and the important part which a university such as this plays in the civic and national life. It is very gratifying, therefore, to me to feel that as a member of this great University I am connected with so important a centre of Scottish life and thought. It is my earnest hope that this ancient foundation will long continue to prosper, and I can assure you that its interest will always lie very close to my heart." Among those present were the Right Hon. Ramsay MacDonald, and Prof. J. Graham Kerr, two of the members of Parliament for the Scottish Universities.

Sir David Prain, C.M.G., C.I.E., F.R.S.

SCIENTIFIC workers in general and botanists in particular will join in congratulations and good wishes to Sir David Prain on the occasion of his eightieth birthday, which he celebrated on July 11. Sir David Prain's career as a botanist began with his appointment as curator to the Calcutta Herbarium some fifty years ago. After twenty-one years' distinguished service to the cause of botany, both pure and applied, in India, Sir David was appointed to the directorship of the Royal Botanic Gardens, Kew, a post which he occupied no less successfully for seventeen years. On the present occasion, however, we think not merely of his many services to the welfare of science but also of his personality that has gained for him both the esteem and the affection of his colleagues. It was this personality and his wise council that rendered Sir David so eminently successful during his presidency of the Linnean Society and of the Imperial Botanical Congress, and caused him to be in so great demand as a chairman. That his kindly charm and valued advice may be long spared to us will be the wish of all his colleagues.

Prof. R. M. Gordon

PROF. R. M. GORDON, professor of tropical diseases of Africa in the University of Liverpool, has been awarded the Chalmers Medal of the Royal Society of Tropical Medicine and Hygiene, which is given annually for research of outstanding merit in tropical

medicine or hygiene. It is one of the conditions of the award that the recipient should be less than forty-five years of age. Prof. Gordon's first experience of medical research in the tropics was in Brazil, where he worked for several years on the Amazon, in the laboratory at Manaus directed by the late Dr. Wolferstan Thomas. After this, he was transferred to the staff of the Sir Alfred Jones research laboratory in Sierra Leone, West Africa, where he has since remained. In 1929 he became director of that laboratory, and in 1930 the University of Liverpool elected him to the chair of tropical diseases of Africa. Prof. Gordon has not been in the fortunate position of being able to select a subject and settle down for a long period of years of quiet research, in a specially equipped laboratory, aided by well-trained laboratory assistants, and free from administrative and financial worries. On the contrary, he has at all times had to carry out many routine duties and has had distracting difficulties and responsibilities with which to contend. When it is remembered also that the whole of his research has been conducted in the trying climate of the worst parts of the tropics, it is a great testimony to his initiative and perseverance that he has succeeded in maintaining a standard of work which compares so well with that of colleagues working in much more favourable circumstances.

DR. GORDON'S first publication was from South America, in the year 1921, and dealt with an experimental investigation into the feeding habits of *Stegomyia calopus*. In 1922 he published a record of the ancylostomes collected at sixty-seven autopsies; it was this early interest in the subject which led soon after to the publication from Sierra Leone in 1925 of a very important paper "On the effect of *Ancylostome*, *Ascaris* and *Trichuris* infection on the health of the West African natives". In bilharziasis, which constitutes a serious menace in large areas of Sierra Leone, as in many other parts of the tropics and sub-tropics, he has made notable advances by the discovery of a focus of *Bilharzia mansoni* infection, and by a very complete experimental study of the mode of transmission, and of the much debated question of the anatomy of the cercariae. His contribution to the study of malaria in many of its aspects, especially as it affects pregnant women in endemic areas, and to the subject of metazoan immunity, assume the greater value the more research on these subjects advances. His latest paper records the discovery of typhus fever in West Africa, a discovery which is clearly destined to have far-reaching results. His investigations into the distribution and bionomics of anopheline mosquitoes in the Freetown area, carried on steadily now for many years, have yielded and will yield valuable data applicable to similar regions throughout the tropics.

General Hertzog and the South African Protectorates

GENERAL HERTZOG, Prime Minister of the Union of South Africa, on his return to South Africa from attending the recent Imperial Conference in London, once more raised publicly the question of the transfer of the administration of the native Protectorates in South Africa from the Imperial Government to the Government of the Union. According to a message, which appeared in *The Times* of July 7, he alleged that the British Government has failed to carry out pledges of early transfer, which were not only conveyed to him personally by the responsible minister on several occasions, but also were embodied in the agreement which formed the substance of the *aide-mémoire* framed and made public in 1935. He went on to assert that instructions issued by the British Government to its administrative officials in the Protectorates have failed to carry out an undertaking to direct those officials to bring their influence to bear on the natives in such a manner as to induce in them an attitude favourable to the transfer to the Union.

MR. MALCOLM MACDONALD, Secretary of State for Dominion Affairs, lost no time in his reply to General Hertzog's criticisms. In a statement to the House of Commons on July 9, he made it clear that not only was there no agreement that transfer would take place within a specified time, but also that when General Hertzog had urged upon him in a personal interview that transfer should begin in the near future, he had pointed out in his reply that the situation described in the *aide-mémoire* had not greatly altered. Further, he went on to indicate that General Hertzog has been kept fully advised of developments in the matter of the Protectorates, not least of the terms of the instructions issued to officials, in which he has fully concurred. Not only did Mr. MacDonald's action meet with the full approval of the House, but also his further reiteration of the pledge that no action in the matter of transfer would be taken without previous consultation of the inhabitants of the Protectorates received its full endorsement.

Grassland Management in Great Britain

IN his presidential address delivered on July 14 to the Fourth International Grassland Congress held at Aberystwyth, Prof. R. G. Stapledon gave an interesting summary of his views concerning the approach to grassland problems in general and also in relation to the special circumstances of grassland management in Great Britain. The most hopeful line of attack on the general problem, Prof. Stapledon believes, is by employment of the regional survey method, as developed by the Aberystwyth workers in their treatment of the grasslands of Wales. The procedure is to map, classify and plan on the basis of natural regions; adapting to each the correct type of implements, fertilizers and especially the correct strains of seeds. The breeding of herbage plants should be carried out in the area for which they are intended, and interchange of genes between

different countries is more likely to be fruitful than interchange of seeds. Of the many factors concerned in the making of useful grassland, the animal is by far the most important; next comes the leguminous plant. Improvement in many instances consists in setting up such soil conditions that a suitable legume will grow, and then adopting a system of management to favour the legume as well as the grazing animal. Then follows the possibility of growing superior herbage plants that had never succeeded before in that area.

TURNING now to some of the special problems of grassland farming in Great Britain, Prof. Stapledon made a strong case for the use of the plough on grassland wherever possible. The method should be to graze hard before breaking up with the view of laying up a store of organic manure or 'stock nitrogen' in the soil. After ploughing a dressing of lime is given, and the accumulated fertility is then in shape to be cashed in the form of some arable crop or immediately put back into still better pasture. Another point of the greatest importance is the production of out-of-season keep. Much has been done lately to conserve summer grass in dried form for winter feeding, but some progress has been made in growing good quality fresh grass for use between December and March. It is a case of species and management. Choosing winter green strains of plants, the grass is heavily manured through the growing stock, further assisted by a little mineral nitrogen, and rested from the end of summer onwards. Working in this way, the Aberystwyth workers have secured on occasions as much as $1\frac{1}{2}$ tons of dry matter per acre with 14-20 per cent of crude protein between Christmas and the end of March. Here again young leys offer more possibilities than permanent pasture.

Archaeological Excavations at Tell Duweir, 1936-37

AN exhibition of antiquities from Tell Duweir, the ancient Lachish, in Palestine, opened at the Wellcome Research Institution, Euston Road, London, N.W.1, on July 12. These antiquities, with an extensive series of photographs of the site and of the work of excavation in progress, represent the results obtained by the Wellcome-Marston Archaeological Research Expedition to the Near East in the season 1936-37. The excavations were again under the direction of Mr. J. L. Starkey. The operations of the season were directed mainly to the investigation of three areas—the north-east corner of the mound on ground rising from the valley to the level of the moat of the Hyksos period; the great rock-cut excavation of shaft discovered in 1935, now ascertained to measure eighty-five feet long by seventy feet broad, with a depth of ninety feet; and the area lying behind the south-west gate, with the rising ground to the east reaching up to the walls of the Jewish palace. In the last-named area, water-borne deposits on the ancient roadway as it descends sharply on approaching the threshold of the inner gate, which had been due to the blocking of the

drainage by the fall of the gateway before assault and conflagration, afforded the first tangible archaeological evidence differentiating the two Babylonian attacks of 597 B.C. and 588 B.C., hitherto not clearly to be distinguished. Tunnels cut in the contents of the great shaft—water-borne deposits, overlying the stones of the collapsed walls of the Jewish city—have as yet afforded no evidence of exits or means of access, nor can the purpose of the shaft yet be determined. Work on this rock-cut shaft, it can be seen, was still incomplete, when it was abandoned, possibly as a result of frontier troubles before the fall of the Jewish kingdom.

A NOTEWORTHY feature among the exhibits is the collection of scarabs, which with the character of the amulets found at Tell Duweir in Sixth and Seventh Century tomb-groups illustrate the persistent influence of Egyptian beliefs and ways of thought among the peoples of southern Palestine. In one of the numerous rock tombs of the north-east corner of the Tell nearly two hundred scarabs of the Eighteenth and Nineteenth Dynasties were found. A continuous series of scarabs with the Royal name now covers the whole period of Egyptian occupation, with the exception of a gap of some fifteen years under Akhenaten and Tutankhamen. One of the most interesting objects in the exhibition, however, is a copper dagger, found in the excavations of 1934, but recently cleaned by the Palestine Museum of Antiquities and on loan by the Palestine Government. It belongs to the Hyksos period and is certainly not later than 1600 B.C. Its interest lies in the fact that it is now seen to bear on one side characters in a pictographic script, affording proof of the development of a script independently of both Egypt and Mesopotamia. With the evidence of these pictographs of the now famous inscribed ewers and of the no less remarkable Lachish letters of the pre-exilic period, of which a detailed study by Dr. Harry Torczyner is now in the press, it is now possible to piece together something of the history of the development of writing in Palestine. The exhibition will remain open until August 7, a cinematograph film of the work of the expedition being shown twice daily; and on July 16 at 5.30, and July 28 at 6 p.m. lectures on the new discoveries will be delivered by Mr. Starkey at the Wellcome Research Institution.

Gold Mining with the Aid of Aeroplanes

Messrs FRASER AND CHALMERS, of Erith, Kent, have recently equipped a gold mine at Progreso in Peru, which is at a height of 12,800 feet above sea-level in an almost inaccessible district about ninety miles south-west of the city of Cuzco. A description of this mine and of some of the difficulties that had to be overcome in transporting the whole of the mine equipment, weighing 150 tons, and the buildings, weighing about 1,000 tons, to the site of the mine is given in the *G.E.C. Journal* (General Electric Co.) for May by W. Bullock. A railway line runs to within about seventy miles of the mine; the connexion between them is a mountain track, which can only

be traversed by mules and llamas, and the journey takes fourteen days to complete. As the track over the mountains is often merely a narrow ledge on the side of a steep hill, it is impossible to carry by animals pieces of machinery or equipment more than 10 feet long. Sectionalizing the plant to this extent rendered this mode of transport impracticable. The engineers therefore chartered and equipped two aeroplanes, each capable of carrying a load of two tons. In this way it was found possible to transport reasonable loads by air. The actual time taken by air was about one hour and that taken by a llama was 14 days. The cost of the latter method, if it had been practicable, would have been one third the cost of transport by air. The ore, after being mined, is reduced in a 'breaker' and brought into the mill on a belt conveyor. It is crushed to pieces of about 2 in. cube size and distributed into a 450-ton crushed ore bin situated behind the stamp mill, which is provided with 24 stamps each having a falling weight of 2,100 lb.

Pollution of Sea and Shore by Oil

For several years, persistent complaints have been made about the damage caused to organisms upon the sea-shore and particularly to birds which frequent the surface by oil discharged from ships. The number of birds whose feathers become so coated with the discharge that they are unable to fly or to dive for food, and in consequence die a slow death from starvation, has been reported to be very great in some years and in some places. From preliminary investigations into the whole subject of oil pollution at sea, Prof. N. K. Adam has written a report, submitted to the Council of the Royal Society, and printed for private circulation, the general effect of which is to allay some of the fears aroused by the earlier records and surmises. In the seas about the British Isles, the principal sources of oil are wrecks, fuel oil accidentally discharged, usually from ballast tanks, and sludge from the cleaning of oil tanks on tankers or oil-burning ships. But the nuisance due to the oil appears to have diminished in recent years, owing partly to the regulations which now prohibit the discharge of oil or oily water near the coast, and partly to the increased use of separators on board ships. A reassuring statement is that fuel oil entirely loses its tendency to spread after a few weeks at ordinary temperatures on a water surface in contact with gravel. On the surface of the sea also it seems to disappear, for it is rare to see an oily film, and it has been found that no appreciable amount is present as an invisible film.

As regards damage caused by oil to marine plant and animal life, the evidence is inadequate and often contradictory. Prof. Adam's impression is that the moderate amount of pollution round our coasts appears to be doing little damage to life, other than birds, either between tide-marks or below low tide level; and that in other places, if there is very heavy and continuous oil pollution, life between tide-marks is seriously affected, but there is not much

evidence of damage below low tide. The impression of the present writer, however, for what it is worth, is that in a limited area where pollution may be high, animals not exposed between tide-marks suffer and may be exterminated, and the supposition was that even if adult sessile forms may be able to withstand pollution, the delicate free-swimming ciliated larvae, by which most sessile forms propagate, succumbed, and multiplication accordingly ceased. But that and several other matters referred to in the report await the test of experiment.

Economic Value of an Experiment in Transplanting

For some seventy years before 1917, the State of Pennsylvania possessed no beavers, and in that year two, imported from Wisconsin, were set free. Between 1917 and 1924, 94 beavers were imported and liberated at a cost of about 50 dollars each. So rapidly did the creatures multiply that it soon became necessary to transfer some to other parts of the State. A survey by the Board of Game Commissioners gives an idea of what the increase meant: in 1931 there were 899 beaver dams with an estimated population of 4,377; in 1934, the population had risen to 15,000. During the trapping season of 1934 the number of beavers taken was 6,455, and the pelts brought the trappers a sum total of 22,610 dollars. Wherever beavers are doing damage, as in farming communities or in irrigation areas, the policy of the U.S. Bureau of Biological Survey has been to encourage and aid in the transference of the animals to carefully selected sites where their dam building may aid in the cause of conservation. To further this policy, the Bureau has published a *Farmers Bulletin* (No. 1768) on "Trapping and Transplanting Live Beavers", in which live-beaver traps are described and trapping methods and transport are discussed for the help of farmers, stockmen, foresters and others interested in beaver control.

An Air-Conditioning Unit

AN air-conditioning unit is usually a small cabinet, the only external evidence of its purpose being two small grilles. In *Engineering* of July 9, a description is given of one meant to stand on the room floor and placed near a window as the air inlet can then be readily arranged. It is about 40 in. high, 30 in. wide and 18 in. deep. It is electrically operated, and the supply cable can be plugged into any existing power point such as one used for a radio cabinet. With the air-cooled type this is all that is required, but with the water-cooled type connexions are needed with the water supply. In both summer and winter, the incoming air is first filtered; the inlet is a permanent fixture and does not interfere with opening the window for cleaning. Otherwise the window is kept closed to keep out the noise of street traffic. The fan is driven by a motor independent of the fans used for cooling and so can provide ventilation without either heating or cooling, if the outside air is in the desired condition. The cooling of the air and the removal of excess moisture by condensation is effected by a special refrigerator. The condensate is

then re-evaporated and carried outside, so no drain-pipe is required in the air-cooled unit. For increasing the moisture in the air, the water in the humidifier tank is vaporized by an electric immersion heater. The relative humidity is settled by a hygrostat which automatically controls the heater. A small neon light indicates when the heating elements are working, and reminds the occupant to consider whether it is advisable to turn off the heat at night when leaving the conditioning plant running.

Atmospheric Pollution

THE twenty-second report on atmospheric pollution contains an account of observations for the year ending March 31, 1936 (London: H.M. Stationery Office, 1937. 6s. net). Reviewing the last twenty years, it is concluded that the effort and propaganda of the period have brought about an appreciable reduction in air contamination. This now seems to have ceased, or even changed to a slight rise, probably on account of the increased industrial activity. Again the figures for some London stations are very high, especially for sulphur. Westminster shows some of the highest figures, and compares very unfavourably with some of the industrial areas. In some cases, remarkable improvements have been rendered over a period of years, and the causes deserve scrutiny. The report is cautious in its interpretation, as the difficulty of sampling is obvious. At Burnley a fifty per cent fall has been recorded in ten years—attributed to the removal of a factory. Attention is directed to the high drop at Wakefield in total deposit, from 613 tons per square mile in 1924 to 227 tons in 1935. This may be associated with the persistent efforts made by the authorities there, and shows what is possible when those who wield political power treat seriously the problem of cleaner air. Unfortunately, it is only too rare that in local authorities the will and wish to improve the atmosphere are combined. The most important development recorded is the initiation of an intensive survey in and around Leicester—selected because it is relatively isolated from other industrial areas likely to prove disturbing factors.

Empire Conference on Tuberculosis

THE Minister of Health, Sir Kingsley Wood, delivered the inaugural address on May 3 at the Empire Conference on the "Care and After-care of the Tuberculous" at Overseas House, St. James's, London. He first reviewed tuberculosis as a cause of mortality in England and Wales. The standardized death-rate from this disease has fallen from 3,638 per million of population in 1851-55 to 687 in 1935; nevertheless, tuberculosis in this country still comes next to cancer in the list of killing diseases. Sir Kingsley next dealt with the public provision for the treatment of tuberculosis—29,000 beds in approved institutions—and the amount of expenditure thereon. He commended particularly the value of village settlements for treatment and after-care, and emphasized the importance of the after-care of patients who did not enter a village settlement.

Tuberculosis (Attested Herds) Scheme

THE Minister of Agriculture and Fisheries has amended the Tuberculosis (Attested Herds) Scheme (England and Wales) dated January, 1935, by the issue of a revised scheme, which came into force on June 1. The purpose of the new scheme, which adheres to the principles of the earlier one, is to encourage the addition of herds to the register of herds officially certified to be tuberculosis-free, by the offer of additional financial inducements to owners of cattle herds to qualify for a certificate of attestation. Further information in regard to the scheme may be obtained from the Secretary of the Ministry, Whitehall Place, London, S.W.1.

International Population Congress at Paris

UNDER the patronage of the International Union for the Scientific Investigation of Population Problems, a congress will be held in Paris for the discussion of these problems on July 29-August 1. The congress is organized by the French National Committee of the Union, under the presidency of M. Adolphe Landry, a former Cabinet Minister. Among the members of the organizing committee may be mentioned, MM. P. Rivet, J. Alquier, H. Bunle, A. Demangeon, M. Huber, R. Legendre, A. Siegfried and other distinguished workers in the field of demography. It is expected that there will be many representative delegations from a large number of countries. From Great Britain there will be members of the British Population Society, presided over by Prof. C. B. Fawcett, and of the Population Investigation Committee, presided over by Prof. A. M. Carr-Saunders, and others. America will send Prof. P. K. Whelpton, Dr. Warren S. Thompson and others. Delegations are also expected from Belgium, Czechoslovakia, Denmark, Germany, Holland, Hungary, Italy, Rumania, Sweden, and perhaps India and Japan.

THE subject-matter of the congress is divided into two main groups: quantitative problems, namely, historical demography, contemporary demography, including existing statistics, movements and international migrations, mortality, fertility and so on, and the resulting economic and social problems; and qualitative problems, namely, biometry, ethnology, transmission of characters, eugenics. Two questions are specially put forward for discussion, namely, (1) "De la meilleure méthode pour dégager et mesurer la tendance du mouvement naturel de la population"; and, (2) "La biométrie différentielle et la biotypologie, comme méthodes pour la classification des individus et des groupes". It is clear that the congress has plenty of work before it. It has been announced that the opening session will be honoured by the presence of the President of the French Republic, M. Albert Lebrun, and will take place at the Maison de la Chimie, 28 rue Saint-Dominique. All inquiries should be addressed to the Congrès International de la Population, 16 rue de l'Estrapade, Paris, V.

Leverhulme Research Fellowships

AMONG the list of Leverhulme Research Fellowships and Grants for 1937 are the following, who will carry out their researches at the places indicated:

RESEARCH FELLOWSHIPS: Prof. D. H. Bangham, professor of inorganic chemistry, Egyptian University, Cairo, the wetting of solid surfaces and the phenomena of spreading liquids thereon (Great Britain); Dr. D. Enid Charles, research fellow, Department of Social Biology, London, the mechanism of population decline with special reference to Scottish population problems (University of Aberdeen); Dr. C. W. Davies, senior lecturer in chemistry, Battersea Polytechnic, adsorption at liquid surfaces (University College, London); O. V. S. Heath, research worker, Institute of Plant Physiology, London, carbon assimilation by the green plant (Imperial College, London); Dr. J. de Graaff Hunter, late director, Survey of India, planning and execution of geodetic triangulation of great extent (renewal of present fellowship) (England); G. W. B. Huntingford, farmer, Kenya Colony, member, Nandi Land Trust Board, Government examiner in Nandi language, sociology of the Dorobo, a forest people of Kenya (Kenya); Dr. J. W. H. Lugg, biochemist, Imperial College, London, preparation and amino acid analysis of pasture plant proteins (Imperial College, London); J. P. M. Prentice, solicitor, meteors and meteor streams (England and North Africa); Dr. H. Scott, assistant keeper, Department of Entomology, British Museum, biogeographical research on the fauna of the highlands of South Western Arabia (Arabia); G. Seligman, chairman, British Group, International Commission of Snow, the transition of firn snow into glacier ice (Switzerland); Dr. H. W. Thompson, departmental demonstrator, Old Chemistry Department, University Museum, Oxford, correlation of data derivable from the spectra of polyatomic molecules with chemical problems (Pasadena).

RESEARCH GRANTS: Dr. D. Elliot Dickson, colliery surgeon, Lochgelly, Fife, occupational morbidity in coal miners (Scotland); Dr. E. M. Lind Hendricks, research worker, Imperial College, London, geological research in Cornwall (Cornwall); G. Manley, senior lecturer in geography, University of Durham, the helm wind of the Northern Pennines (England); Dr. R. E. Mortimer Wheeler, keeper, London Museum, origins in northern France of later prehistoric civilizations of Britain (France); Dr. M. Wilson, reader in botany, University of Edinburgh, a comparative study of the diseases of the Douglas fir in Europe and North America (Canada).

Beit Memorial Fellowships

THE following elections have been made by the trustees of the Beit Memorial Fellowships for Medical Research:

FOURTH YEAR FELLOWSHIPS (value £500 a year): Dr. R. P. Cook, to continue his research on cholesterol metabolism in reference to the cause of atheroma in blood vessels (at the Institute of Biochemistry, Cambridge); S. L. Cowan, to continue his research on the neuro-muscular transmission of nervous

excitation (at the Department of Pharmacology, University College, London); Dr. D. E. Green, to continue his studies on intracellular enzymes and on the influence of vitamin B on oxidation processes (at the Institute of Biochemistry, Cambridge); Dr. M. Jowett, to continue his study of the action of narcotic drugs on the metabolism of the central nervous system (at the Biochemical Laboratory, Cardiff City Mental Hospital).

JUNIOR FELLOWSHIPS (normal value £400 a year): I. A. Anderson, for research on iron analyses of diets of women of the poorer classes at Aberdeen, and studies on the treatment of anaemia (at the Metabolic Research Laboratory, Aberdeen Royal Infirmary); Dr. D. Beall, for work on sterol metabolism, with special reference to sex hormones (at the Department of Pathology, British Postgraduate Medical School, London); J. G. Chalmers, for work on the role of polycyclic hydrocarbons in experimental tumour production (at the Glasgow Royal Cancer Hospital); Dr. F. C. Courtice, to study the influence of insulin and endocrine secretions on the metabolism of prolonged muscular exercise (at the Physiology Laboratory, Oxford); H. Davson, to study the cause of primary chronic glaucoma of the eye (at the Department of Physiology and Biochemistry, University College, London); Dr. T. R. R. Mann, for research on intracellular compounds of blood pigment and the metabolism of oxalic acid in mammalian tissue (at the Molteno Institute, Cambridge); Dr. Antoinette Pirie, to study the metabolism of filterable organisms by analysis of their enzyme systems (at the Institute of Biochemistry, Cambridge); Dr. D. Richter, for work on the action of adrenaline and related substances on the metabolism of individual organs (at the Institute of Biochemistry, Cambridge).

Travelling Fellowships in Tuberculosis

THE Medical Research Council has awarded Dorothy Temple Cross research fellowships to the following, who intend to study problems of tuberculosis at centres abroad, during the academic year 1937-38: Dr. B. C. Thompson, formerly assistant tuberculosis officer, Durham County Council (renewal of present fellowship for three months); R. H. R. Belsey, resident surgical officer, Hospital for Consumption and Diseases of the Chest, Brompton, London; Dr. B. M. Maxwell, senior assistant medical officer, Cheshire Joint Sanatorium, Market Drayton; O. S. Tubbs, chief assistant to a Surgical Unit, St. Bartholomew's Hospital, London; Dr. Enid M. Williams, assistant lecturer in tuberculosis, Welsh National School of Medicine, Cardiff.

British Empire Cancer Campaign

THE quarterly meeting of the Grand Council of the British Empire Cancer Campaign was held on July 12. On the recommendation of the Scientific Advisory Committee, the following grants were approved: £500 to Dr. P. M. F. Bishop, at Guy's Hospital, for the expenses for one year of certain investigations in regard to endocrine therapy in relation to cancer; £250 to Prof. G. I. Finch, at the Imperial College of

Science and Technology, for the expenses of an investigation, on behalf of the Scientific Advisory Committee, into the nature and structure of carcinogenic compounds; and £180 to Dr. P. R. Peacock, at the Glasgow Royal Cancer Hospital, for the purchase of special apparatus for the continuation of his cancer research. On the recommendation of the Joint Committee of the Campaign and of Mount Vernon Hospital, Dr. G. Cranston Fairchild was re-appointed the William Morris research fellow in radiology at that Hospital for a further period of one year. The William Morris research fellowship was established five years ago by a generous donation of a capital sum of £25,000 by Lord Nuffield.

Occultations of Mars and Venus

IF the evening sky is clear on July 17, an interesting observation can be made without a telescope (though, preferably, slight optical aid is desirable) of the occultation of the planet Mars by the moon. The disappearance of Mars, as seen from a station near Greenwich, takes place at the moon's dark limb (the age of the moon being 9.7 days) at position angle 53° from the north point of the disk, measured eastwards, at $21^h 13^m$ U.T. ($22^h 13^m$ Summer Time). The reappearance of Mars at the moon's bright limb is at position angle 326° at $22^h 10^m$ U.T. or $23^h 10^m$ Summer Time. The apparent diameter of Mars is about $14''$ and its stellar magnitude -0.8 . A map in the B.A.A. Handbook for 1937 gives the limits on the earth's surface of the visibility of this occultation. The occultation of Venus by the moon on August 3 takes place in full daylight and cannot, in any event, be seen from southern England. The southern limit of visibility of partial occultation, as given in *J. Brit. Ast. Assoc.*, March, p. 187, runs approximately between Hull, Bradford and a little north of Blackpool; the southern limit of total occultation runs from just south of Bridlington, to Borough Bridge and just north of Carnforth. At Edinburgh, the disappearance of Venus is due at $8^h 26^m$ U.T. at position angle 159° from the north point of the moon's disk, and the reappearance at position angle 212° at $9^h 1^m$ (add 1^h to convert to Summer Time). The phenomenon will require telescopic aid generally, though Venus can on occasions be 'picked up' in daylight by keen-sighted observers. The moon's age is 26.2 days, so that the crescent is a very narrow one. Venus is in its gibbous phase, the ratio of the illuminated area of the disk to that of the entire apparent disk ($17''$ in diameter) being 0.67. Its stellar magnitude is -3.6 . The position of Venus on August 3 at 9^h is R.A. $5^h 53^m.0$; Dec. $+21^\circ 20'$.

A New Comet (1937 f)

A NEW comet was discovered on July 4 not far from the star, β Persei (Algol), by Mr. Finsler at Zurich. At discovery, the comet was diffuse without a central condensation of nucleus, but two days later, according to an observation made at Barcelona, a nucleus was observed as well as a short tail somewhat more than 1° in length. The *International*

Astronomical Union Circular No. 664 from Copenhagen gives elements of the comet derived from observations made at several observatories from July 4 to July 7. Independent elements of the comet's orbit are derived by Möller (Copenhagen), Kwiek (Poznań) and Cunningham (Harvard). These elements give the time of perihelion passage, respectively, as August 12.435, 11.139 and 14.52 U.T. The ephemeris derived from Möller's elements gives the position of the comet at 0^h U.T. on July 14, 18 and 22 as follows:

	R.A.	N. Decl.
July 14	3 ^h 17.5 ^m	45° 43'
18	3 ^h 25.6 ^m	40° 50'
22	3 ^h 39.1 ^m	55° 31'

Dr. Steavenson has already observed this comet, which promises to be an interesting object. Its present magnitude is 7, but the decrease in its present heliocentric and geocentric distances, 1.05 and 1.25 units respectively, will probably cause a considerable increase in brightness.

Announcements

THE first award of the Johannes Schmidt Medal has been made to Mr. Henry G. Maurice, fisheries secretary of the Ministry of Agriculture and Fisheries, and president of the International Council for the Exploration of the Sea, in recognition of his great services to international oceanographical and fisheries research. Most appropriately the presentation, by H.R.H. Prince Waldemar of Denmark, was made in the new offices of the Council in Charlottenlund Slot, on the occasion of the thirteenth annual meeting of the Council, which was held on July 5-10.

IN connexion with the centenary celebrations of the University of Athens (see *NATURE*, May 1, p. 749), the honorary degree of doctor of science was conferred upon Sir Napier Shaw, formerly director of the Meteorological Office and honorary president of the Commission for the Exploration of the Upper Air.

THE following officers have been elected to the Council for the year 1937-38 of the Institution of Electrical Engineers: *President*, Sir George Lee; *Vice-Presidents*, Sir Noel Ashbridge, Mr. J. R. Beard; *Hon. Treasurer*, Mr. W. McClelland.

THE following, among others, were granted Civil List pensions during the year ended March 31, 1937: Mrs. Jessie Bennett, in recognition of the services rendered by her husband, the late Mr. Arthur Bennett, to botanical science (£80); Dr. Maurice Copisarow, in recognition of his services to science, and in particular to chemical research (£130); Mrs. Elizabeth MacKenzie, in recognition of the services rendered by her husband, the late Mr. Donald MacKenzie, to the study of anthropology, mythology and folk-lore (£70).

THE following appointments have recently been made in the Colonial Service: R. A. Wright, veterinary officer, Malaya; R. J. A. W. Lever (entomologist, British Solomon Islands Protectorate),

entomologist, Fiji; C. Swabey (assistant conservator of forests, Trinidad), forestry officer, Jamaica; K. J. Johnston (superintendent of surveys), assistant surveyor general, Ceylon; A. V. Lawes (surveyor, Tanganyika), surveyor, Gold Coast; H. M. W. Nicholson (assistant pharmacist), pharmacist, medical department, Tanganyika; H. F. Rainsford (staff surveyor, Tanganyika), computer, survey department, Uganda; W. F. Wegener (assistant chief mechanical engineer), chief mechanical engineer, Federated Malay States Railways; W. W. Williams (assistant superintendent), superintendent of surveys, Ceylon; L. G. O. Woodhouse (assistant surveyor general), deputy surveyor general, Ceylon.

PROF. PAUL MONTÉL, professor of the theory of functions and theory of variability at the Sorbonne, has been elected a member of the Section of Geometry of the Paris Academy of Sciences, in succession to the late Prof. E. Goursat.

M. LÉON GUILLET, director of the École Centrale des Arts et Manufactures, and professor at the Conservatoire des Arts et Métiers, Paris, has been nominated an honorary vice-president of the Iron and Steel Institute.

PROFS. JULIUS BORDWIJ, director of the Pasteur Institute of Brussels, and Pierre Nolf, president of the Red Cross, have been awarded the Grand Cross of the Order of Leopold.

DR. RUFUS COLM, director of the Hospital of the Rockefeller Institute for Medical Research since 1909, has retired. His successor is Dr. Thomas Milton Rivers, who has been a member of the board of scientific directors of the International Health Division of the Rockefeller Foundation since 1927.

THE Paul Appel Prize and Gold Medal of the Renaissance française, for the best contribution in recent years to the campaign against social scourges, has been awarded to the French League against Cancer for the "Index Analytique Cancérologique", commenced eleven years ago under the scientific direction of MM. Forgue, de Nobile, Hartmann, Rogard and Roussy. The recipients of the prize are MM. Lacazeagne and Lavedan, general secretaries of the League.

A "Catalogue of Books and Journals on Zoology, Biology and Geology" (No. 507) for sale by W. Heffer and Sons, Ltd., Cambridge, contains 1,886 items. General works and scientific journals are well represented, as also are the groups dealing with entomology, ornithology and geology.

IN connexion with the notes on national and international standardization in *NATURE* of July 3, p. 19, we are asked to state the Survey to which they refer can be obtained from the Central Office of the World Power Conference, 36 Kingsway, London, W.C.2, price 3s. 6d., or 3s. 8d. post paid; copies may also be ordered through any bookseller.

non-specific activated diffusion. The data needed to test this hypothesis were available in papers by Edwards and Pickering³, and by Dewar⁴. Graham⁵ first noted the large temperature coefficient of the diffusion process through rubber, and that the diffusion velocities had no connexion with the molecular weights.

Edwards and Pickering's data for the diffusion of hydrogen, helium and carbon dioxide through vulcanized rubber, and Taylor, Hermann and Kemp's data⁶ for the diffusion of water through vulcanized rubber, give good straight lines when log (diffusion rate) is plotted against the reciprocal of the absolute temperature (T), with the exception of the data for carbon dioxide at temperatures of 80° and 100° C. Similarly Dewar's data (Fig. 1) for diffusion of hydrogen, helium, carbon monoxide, carbon dioxide and oxygen through pure para-rubber, give linear log (diffusion rate) vs $1/T$ curves. Energies of activation calculated from these curves for vulcanized and for para-rubber are given in the accompanying table. They are very much larger for the pure para-rubber than for the vulcanized rubber.

VULCANIZED RUBBER

PARA RUBBER

Gas	Energy (cal./mol.)	Author	Gas	Energy (cal./mol.)	Author
He	6,800	Edwards and Pickering	He	15,400	Dewar
H ₂	6,470	"	H ₂	19,000	"
	5,900	Daynes ⁷			
CO ₂	7,580	Edwards and Pickering	CO ₂	19,100	"
H ₂ O	2,780	Taylor, Hermann and Kemp	O ₂	16,300	"
			OO	19,000	"

The solubility of these gases in rubber varies only slightly with temperature⁸, so that no explanation save one involving activated diffusion can account for the velocity increasing exponentially with temperature.

Nitric Oxide and Alkyl Ethers

THE reaction of dimethyl ether and nitric oxide has been investigated in some detail by Dr. P. F. Gay and myself¹, and whatever the mechanism of the secondary reaction which follows the suppression of the main decomposition process may be, it seems to be quite clear that it cannot be the one represented by the equation,

since the ratio, $(\text{CO} + \text{CO}_2)/\text{CH}_4$, in the product is the same as when nitric oxide is absent from the system. What does happen is that the ratio CO_2/CO

is greater when nitric oxide is present than when it is absent, and in the presence of nitric oxide the product contains very little free hydrogen. It seems likely, therefore, that the mechanism suggested by Dr. Gay and myself¹ explains the effect of the nitric oxide better than that put forward by Messrs. Thompson and Meissner in *NATURE*² of June 12.

I may point out that nitrous oxide is also certainly a product of the process, and it is interesting to note that ammonia, or an amine, is also formed. However, the significance of this observation will only be arrived at by quantitative study of an exacting character, which will be difficult.

As Dr. Gay and I have pointed out, the interaction of nitric oxide and the ethers is a particular instance of a common phenomenon involving the retardation or suppression of one process and the acceleration or initiation of another. Similar reactions have been studied in this laboratory.

Structure and Resistance of Thin Metal Films

IT was proposed by Kramer¹ that a film below a certain 'transition temperature' is mainly amorphous, though containing some regions of normal metal, and that at the transition temperature the film is converted completely into the normal crystalline metal. The transition temperature was given by an empirical formula in terms of atomic volume, conductivity, and the number of free electrons per atom (N) in the normal metal. Structural changes have been shown to occur by different investigators², and have been discussed by them and others³. It has not always been observed that the structural changes occur at a sharply defined critical temperature, and theories alternative to that of Kramer have been proposed.

It does not appear to have been remarked that the resistance-temperature curve shown by Coslett⁴ indicates a transition temperature at about 10° C. for indium. If we take for indium $N = 3$, then Kramer's formula indicates a transition temperature of 282° K., which is in excellent agreement with Coslett's curve. Kramer takes $N = 3$ for aluminium, which would justify the use of $N = 3$ for indium, although Hume-Rothery prefers $N = 1$ in each case⁵. The transition temperature of 282° K. would not agree with the recent proposal of Fukuroi⁶ that the 'recrystallisation' temperature is 0.4 multiplied by the melting point, since the melting point of indium is 428° K., and the zero-thickness transition temperature would be higher than 282° K.

On the other hand, this agreement with Kramer's theory may be fortuitous, since, setting $N = 1$ in his formula, we obtain for rubidium and caesium transition temperatures of 80° K. and 117° K. respectively. The work of Lovell⁷ on rubidium covered the range 64°-90° K., and showed not only no transition point but a resistance-temperature curve with a positive slope, while caesium⁸ showed similarly a positive slope, which would not be expected below the transition temperature.

It seems possible that the existence of a sharp transition temperature may be associated with the desorption of gas from a film originally formed under poor vacuum conditions, or on a substrate not free from gas, owing either to the existence of a critical temperature for gas desorption or to a delay of recrystallization owing to the presence of gas. That gas may be important under high vacuum conditions (10^{-4} mm.) has been shown here in work on the high-frequency resistance of thin molybdenum films deposited on glass. High-frequency resistance is insensitive to large-scale structural changes, for example, to formation of cracks and fissures, and even to the formation of 'windows'. Nevertheless, there is an increase in film resistance with time unless the glass has been thoroughly degassed by prolonged baking.

the pressure change will be a measure of the change in quantity of gas. If, therefore, within the diver processes take place involving liberation or absorption of gas, the rate of these processes may be estimated quantitatively by measuring at different times the pressures at which the diver is in (unstable) equilibrium at a fixed level.

Fig. 1 shows how this may be done on an ultra-micro scale. *A* is a diver of the simplest type and with a gas volume of approximately 10 c.mm. In the bottom of the bulb 1 c.mm. of reaction mixture (*R*) is placed, and in the neck there is a small stopper of paraffin oil (*O*). *T* is a glass tail which serves as a weight to maintain the diver in a vertical position and to regulate its equilibrium pressure at a value close to that of the atmosphere. The diver is placed in a vessel *B* filled with saturated ammonium sulphate (to reduce gas exchange to a minimum without increasing viscosity). *B* is submerged in a well-regulated thermostat ($\pm 0.02^\circ$) and connected with the manometer *M* and pressure adjuster *P*. The latter consists of a syringe the piston of which is moved by means of a rack. The manometer and the syringe are filled with water. By pressing the piston up and down it is possible to bring the diver to a temporary standstill at the mark *F*, and the corresponding pressure observed on the manometer is reproducible within 0.2 cm. water. Since this uncertainty is 0.02 per cent of the total pressure (about 1 atm.), any variation of the quantity of gas within the diver may be measured with an accuracy of $\frac{10 \times 0.02}{100}$ c.mm.

Furthermore, the equilibrium pressures of two different divers kept in two different vessels for a period of 24 hours will not change mutually by more than 0.2 cm. water.

The principle has been successfully applied to the study of choline esterase activity using the Warburg technique (change of carbon dioxide tension over bicarbonate buffered reaction mixtures). But it is also applicable to the study of respiration and generally in many cases where gasometric analysis is used.

Details and applications will be described in subsequent papers.

On Bremsstrahlung

THE method previously used¹ to calculate the cross-section for pair production by a beam of γ -rays has been extended to deal with transitions of a Dirac electron between two states of positive energy in a Coulomb field. It is thus theoretically possible to obtain an exact evaluation of the differential cross-section for energy loss by radiation of an electron incident on an atomic field (neglecting screening, which is justifiable for the energy values used). Actually, owing to difficulties of computation, the calculation is only practicable for fairly slow electrons losing more than half their kinetic energy in the field of a heavy nucleus. This is the case in which the values calculated by the use of Born's approximation² may be expected to be least reliable. The numerical work involved in the exact solution is too heavy to

Principle of the Cartesian Diver applied to Gasometric Technique

If for some reason or other the quantity of gas in a Cartesian diver decreases or increases, the

Fig. 1.

pressure necessary to bring the diver to a standstill at a fixed level will change correspondingly, that is,

allow a full survey of the low energy region, so in order to check the Born values in this region the differential cross-section (per unit energy range of the final state) has been calculated in two particular cases, for lead ($Z = 82$) for an incident electron of total energy $E_0 = 3mc^2$, losing energy $h\nu = 1.5mc^2$ and $1.95mc^2$.

The cross-sections Φ are given for these two cases and for comparison the values obtained using the Born approximation are inserted (Bethe and Heitler, *loc. cit.*, eqn. (15)).

Energy loss	$1.5mc^2$	$1.95mc^2$
$\Phi \times 10^{24}$	13	8
$\Phi \times 10^{24}$ (Born)	9.9	1.8

The values given should be correct to about 10 per cent. It appears that in this case the Born approximation gives fairly good results, except towards the short wave limit, $h\nu \rightarrow E_0 - mc^2$, where it is much too low. This is to be expected, as the wave function of the electron in the final state can no longer be regarded as an approximately plane wave.

As suggested by Heitler², it can also be shown that for the Dirac electron, as in the non-relativistic theory of Sommerfeld, the cross-section approaches a finite value at the short wave limit. We may expect that, as in the analogous case of pair production by a beam of γ -rays³, the error of the Born values will decrease rapidly with increasing E_0 and decreasing atomic number, except near the short wave limit.

Comparison with experiment is as yet impossible, but it may be noted that Klarman and Bothe⁴, using electrons of mean total energy about $3.5mc^2$ scattered in xenon and krypton, have obtained results indicating energy losses about 3-5 times those given by the Born approximation.

Absorption Spectra Evidence of the Decomposition of the Ground Term of Nd^{+++} Ion due to Crystalline Fields

PARAMAGNETIC ions in crystals are subject to electrostatic crystalline potentials the symmetry properties of which depend mainly on the local arrangement of other atoms around the ion. For example, six oxygen atoms grouped octahedrally around the ion, as in $NdCl_3 \cdot 6H_2O$ and $Nd_2(SO_4)_3 \cdot 8H_2O$, give rise to a field of cubic symmetry of the type $D(x^4 + y^4 + z^4)$. A general method for determining the decomposition of the energy levels of the ion in such a field has been worked out by Bethe¹, and Van Vleck² has utilized this theory to account for the broad features of the temperature variation of the magnetic susceptibility of crystals. Penney and Schlapp³ have considered the rare earth salts in detail. From the temperature variation of the mean susceptibility, as measured by Gorter and de Haas, they find that the level $^4I_{5/2}$ of the free ion is split into three groups of levels at 0, 244 and 610 cm^{-1} . Spedding⁴, by direct spectroscopic measurements of the absorption spectra of this crystal, finds levels at 0, 77 and 260 cm^{-1} . From these results the conclusion is drawn that the levels predicted by Schlapp and Penney are not found, but the levels actually

observed have the same relative, but only one third overall, separation. Determining the value of the constants in Penney and Schlapp's equations, Spedding finds that his results are in better agreement with the susceptibility measurements of Zernicke and James, and of Selwood.

I wish to report on the result of certain investigations carried out in my laboratory by Mr. P. C. Mukherji on the absorption spectra of crystals of $NdCl_3 \cdot 6H_2O$, which are in good agreement with the predictions of Penney and Schlapp's theory. The detailed results are being published in the *Indian Journal of Physics*. It has been found that in the region of 5000 Å., there is an absorption band consisting of seven intense lines, and accompanied on the longer wave-length side by a similar group of six faint absorption lines.

Strong lines	Weak lines	Interval
19,144 cm^{-1}	18,897 cm^{-1}	247 cm^{-1}
19,095	18,852	243
19,062	18,820	242
19,035	18,788	247
19,001	18,752	249
18,973	—	—
18,940	18,691	249
	Mean	249 cm^{-1}

On reducing the temperature of the crystal to that of liquid oxygen, it is found that while the sharpness of the faint components increases, their intensities diminish, so that they can be observed at the low temperature with a comparatively thick crystal only ($t = 2.5$ mm.). The weak lines seem, therefore, to be due to transitions from a lower excited level of the ground term of the Nd^{+++} ion, and the observed frequency difference of 249 cm^{-1} seems to be in good agreement with the calculated value of 244 cm^{-1} found by Penney and Schlapp. This result appears to be a definite optical verification of the splitting up of a term in a crystalline field as calculated from purely magnetic data.

D. M. BOSE.

³ *Phys. Rev.*, **41**, 194 (1932).

⁴ *J. Chem. Phys.*, **5**, 160 (1937).

THE interpretation of the absorption spectra of rare earth crystals, as given by Spedding and his collaborators¹, and by Prof. Bose in the above letter, to us seems too simple to be true. Spedding claims that his measurements on the absorption spectrum of crystals of the type $X_2(SO_4)_3 \cdot 8H_2O$, where X is a rare earth element, can be quantitatively explained on the basis of a crystalline potential $D(x^4 + y^4 + z^4)$. In the case of Pr^{+++} , for example, this potential by no means removes all the degeneracy of the lowest state, $^4H_5$, of the free ion, but gives a pattern consisting of a single, a doubly-degenerate, and two triply-degenerate levels. Spedding actually finds four low-lying levels, and identifies them with this pattern. As he points out, any terms in the potential function not of cubic symmetry will remove the degeneracy of the triple levels in first approximation, and the fact that no trace of such doubling or tripling can be detected, he takes to mean that terms other than those of cubic symmetry are practically absent.

The validity of the assumption of a crystalline field of almost perfect cubic symmetry can be tested with considerable accuracy by an appeal to magnetic data, since any deviation from cubic symmetry causes anisotropy in the paramagnetic susceptibility. At room temperatures, for the rare earths (anisotropy/mean susceptibility) must be of the same order as (splitting caused by non-cubic terms in a triply degenerate cubic level/overall splitting due to cubic field). Prof. K. S. Krishnan has kindly informed us that $\text{Pr}_2(\text{SO}_4)_3 \cdot 8\text{H}_2\text{O}$ at room temperatures has an anisotropy roughly 10 per cent of the mean susceptibility*. Hence, separations of at least 50 cm^{-1} must be assumed between the various components of either of the two triply degenerate cubic levels of Pr^{+++} in order to account for the magnetic measurements. All nine levels of $J=4$ should show up in absorption spectra, and the failure of Spedding to locate more than four may simply mean that at room temperatures these are the only ones with any appreciable population. Again, the explanation may very well lie in peculiar intensity rules, at present not understood.

We have made further calculations on the mean susceptibility and anisotropy of $\text{Pr}_2(\text{SO}_4)_3 \cdot 8\text{H}_2\text{O}$, and the corresponding salts of neodymium and ytterbium. Roughly the same cubic fields, together with small rhombic terms give satisfactory agreement for Pr^{+++} and Yb^{+++} , and for Nd^{+++} at all but very low temperatures. At these temperatures, as pointed out by Van Vleck², small departures from cubic symmetry can only have the effect of *increasing* the susceptibility of Nd^{+++} , whereas the experimental results are considerably *lower* than those predicted by a field of cubic symmetry. We find that if the rhombic field is made sufficiently large to lower the mean susceptibility of Nd^{+++} to the observed value, all resemblance of the energy diagram to the cubic field pattern is lost.

Details will be published elsewhere.

Band Spectrum of Chromium Hydride, CrH.

CONTINUING our investigations of the spectra of the hydrides of the transition elements, we have now observed a band in the region 3600–3700 Å. when running a high-tension arc between chromium electrodes in a flame of hydrogen burning in air.

Fig. 1.

The method of production of this band is similar to that used by us to obtain the spectra of nickel hydride¹, NiH, and manganese hydride², MnH, and we attribute the new band to CrH. A spectrogram taken in the first order of a 20 ft. concave grating is reproduced in Fig. 1. The band is degraded to

shorter wave-lengths, and the rotational structure is only partially resolved under this dispersion.

The chromium oxide, CrO, bands in the orange region of the spectrum were not observed under the conditions most favourable for the production of the new band, and it seems very unlikely, for experimental reasons, that the band can be due to anything except the hydride. The chromium atom has a ³S level as its lowest state, and a high multiplicity, probably six, is therefore to be expected for the hydride; this would account for the complexity of the rotational structure of the band.

Nuclear Moments of Aluminium

THE hyperfine structure of the lines $3^2P_{1/2} - 4^2S_{1/2}$ (3944 Å.), $3^2P_{3/2} - 4^2S_{1/2}$ (3961 Å.), $3^2P_{1/2} - 3^2D_{3/2}$ (3082 Å.) and $3^2P_{3/2} - 3^2D_{5/2}$ (3093 Å.) was investigated by means of the absorption in an atomic beam of aluminium. The structure of the lines $3^2P_{3/2} - 4^2S_{1/2}$ and $3^2P_{3/2} - 3^2D_{5/2}$ could not be resolved. The line $3^2P_{1/2} - 4^2S_{1/2}$ was found to possess three components at -0.048 , 0.000 and $+0.048 \text{ cm}^{-1}$ of approximately equal intensity. The line $3^2P_{1/2} - 3^2D_{3/2}$ possessed two components, their separation being 0.062 cm^{-1} ; the intensity ratio of these two components was measured to a high degree of accuracy; the mean of eighty measurements gave the value 1.21, the component of longer wave-length being the stronger.

From the observed structure of the line $3^2P_{1/2} - 4^2S_{1/2}$, it follows that the levels $3^2P_{1/2}$ and $4^2S_{1/2}$ are both split into two levels, of separation 0.048 cm^{-1} (the greater splitting of the line $3^2P_{1/2} - 3^2D_{3/2}$ is due to a small unresolvable inverted structure of the level $3^2D_{3/2}$, which is probably caused by perturbation by the term $3s3p^2^2D_{3/2}$). The observed intensity ratio of the components of 3082 Å. gives a value 9/2 for the nuclear spin, the theoretical value for a spin 9/2 being 1.22. The magnetic moment, calculated from Goudsmit's formula, is 4.1 nuclear magnetons according to the splitting of the level $4^2S_{1/2}$ and 3.6 nuclear magnetons according to the splitting of the level $3^2P_{1/2}$. The agreement between these two values is the more satisfactory as the formula for p -terms gives, according to Goudsmit, rather too low values for light elements.

The lines $4^2S_{1/2} - 5^2P_{1/2}$ (6696 Å.) and $4^2S_{1/2} - 5^2P_{3/2}$ (6699 Å.) were observed in emission; they were both doublets, only just resolvable on account of the Doppler width, of separation about 0.05 cm^{-1} ; the intensity ratio, when corrected for overlapping, was found to be about 1.23, the long wave component being the stronger. These observations are in agreement with the above conclusions.

This result is in disagreement with the contents of a preliminary note by Ritschl¹; from an observed doublet hyperfine structure in the lines 3057 and 3050 of the arc spectrum and 2669 of the spark spectrum, he suggested a nuclear spin of 1/2; but he made no intensity measurements, and the observed doublet structures can be explained by incomplete resolution.

Aggregation of Virus Particles

EVIDENCE confirming the description¹ by Bawden *et al.* of the shape of the tobacco mosaic virus particle appears in Best's recent photograph² of virus protein forming long threads after it has been precipitated from solution. Further evidence that virus particles, even in dilute solutions, may form chain aggregates is obtained from experiments on the relation between dilution of virus and number of infections caused.

Certain carefully purified preparations of virus³ gave, on dilution, infection series which agreed closely with an equation of the form $y = N(1 - e^{-px})$, where y is the number of infections produced by an inoculum of relative concentration x , N is the asymptotic number, n_1 is the number of virus particles in the undiluted preparation, and p is the small probability of any one particle entering one of the N points in the plant tissue to cause an infection.

In the example given of a dilution series for a purified sample of tobacco mosaic virus (ref. 3, Table 1) there was a significant divergence from the values calculated from the equation; and the results since published by Stanley^{4,5} for crystalline tobacco mosaic and aucuba mosaic proteins are widely divergent from calculated values. The number of infections increases less rapidly with concentration of virus than would be expected. In attempting to explain such divergences, we assumed that the virus particle was capable of combining reversibly with a particle of impurity to give an inactive complex. The relation between the concentration of effective virus particles, n_1x , and the total concentration, v_1x , is given by

$$(n_1x)^2 + n_1x(k - v_1x(1 - q)) - v_1xk = 0,$$

where q is the ratio of the number of particles of impurity to the number of virus particles and k is the dissociation constant of the complex. The special form of the equation which fitted the results was that when $q = 1$. This seemed to be a highly unlikely state of affairs. Search for a more likely hypothesis revealed the fact that the same equation is obtained if it is assumed that virus particles can join end-to-end to form chains, single particles or aggregates being infective units. If r is the number of junctions between particles, then using the above nomenclature,

$$r = v_1x - n_1x;$$

and if k_1 and k_2 are independent of chain length

$$k_1(n_1x)^2 = k_2r = k_2(v_1x - n_1x) \\ (n_1x)^2 + kn_1x - kv_1x = 0.$$

The infection-dilution data for a number of experiments with viruses of the tobacco mosaic group and Stanley's results with purified virus proteins^{4,5} have been tested by applying this modifying equation. The former were obtained with virus preparations at various stages of purification, but in all cases the agreement between observation and calculation is sufficiently accurate to render it likely that end-to-end aggregation is the main cause of the divergence of the results from expectations based on the simpler picture of separate virus particles.

It may be expected that the modified picture will apply only to the tobacco mosaic group of viruses,

which are thought to consist of rod-shaped particles⁶, and this has so far been borne out by experiment.

These results are described more fully in a paper to be published in the *Australian Journal of Experimental Biology and Medical Sciences*.

Production of Mutations by Neutrons

IN experiments to determine the possibility of producing mutations by treatment with neutrons, adult males of *Drosophila melanogaster* were subjected to a neutron bombardment derived from a 485 gm. block of beryllium exposed to the γ -rays from 4 gm. of radium. It is known that beryllium thus exposed produces neutrons of two velocities, the fast ones having an energy of 0.60 million electron-volts and the slow of 0.16 million electron-volts. Fast neutrons were used in one series of experiments, the very slow ones being excluded by means of a cadmium plate. In a second series, the fast neutrons were slowed down by passage through paraffin, so that only slow neutrons were used. In a third series, serving as a control, paraffin was substituted for the beryllium block, so that the flies received no neutrons but did receive the same gamma radiation and secondary radiation from the radium source as in the first two series. In these three series, a thick lead block was used to remove most of the radium γ -radiation. Finally, in a fourth series, serving as a second kind of control, the flies were not irradiated artificially in any way.

The CLB method of breeding was used, and the occurrence of all sex-linked lethals was noted. The table below gives the summarized results of the examination of the F_2 groups of flies (15,352 fertile cultures in all).

Series	No of Groups of F_2	No of lethals	Observed frequency of lethals
1. Fast neutrons plus escaping radium radiation	4312	44	1 in 98
2. Slow neutrons plus escaping radium radiation	1504	5	1 in 301
3. Escaping radium radiation without neutrons	4764	19	1 in 250
4. No irradiation	4772	12	1 in 398

It will be seen that although the radiation escaping from the radium source may have caused a few mutations, this by no means accounts for all the mutations arising in the flies treated with fast neutrons. On the other hand, the slow neutron series did not have an appreciable number of mutations produced in it, although, from a theoretical point of view, some production of mutations by this means also is to be expected.

The mutations produced by the fast neutrons probably result from the action of the recoil protons and other atomic nuclei, in producing ionization along their tracks. This effect then falls in line with that of gamma and X-rays, of fast electrons, of ultra-violet and of alpha rays, in producing mutations, being most nearly akin to that of the last-named agent.

A more detailed account of the physical arrangements and of the results obtained is in course of preparation. We wish to express our thanks to Prof. Edgar Altenburg, under whose encouragement and guidance on the genetic side the work was carried out. We wish also to thank the American Oncologic Hospital of Philadelphia for the use of its 4 gm. radium bomb.

A Short Periodic Growth Cycle and a Secular Variation in *Lemna minor*

THE rate of frond production in *Lemna*, when grown under constant conditions in which light, temperature and culture solution were all controlled, was found to be only approximately exponential and certain deviations from the ordinary compound interest law have been established. First, there is a secular variation which takes the form of a wave with a 25-35 day cycle and, secondly, superimposed on the long variation is a short periodic cycle of 4-8 days. The short wave has been followed through 15 successive cycles in one experiment. The length of the cycle of the short, and possibly also of the long wave, appears to be correlated with the mean rate of increase in frond number, in that when grown under conditions which give rise to a rapid rate of division the cycle is short, and vice versa.

Successive measurements of dry weight show a secular 'wave' as in the case of the rate of increase in frond number. The waves in both cases are of approximately equal lengths in any one experiment, but are opposite in phase. The presence of a short periodic cycle in dry weight determinations has not been definitely established, but the data available indicate its probability.

The experiments show that, while there is neither constancy in the dry weight per frond nor in the relative rate of increase in frond number, yet the rate of increase of total mass appears to be strictly exponential.

Little is known of the factors influencing the rhythmic increase in frond number and variation in dry weight, but they may be related to the fact that the growth data are those of colonies of numerous individuals, that is, that there is a social biological effect. This aspect of the matter is now undergoing investigation.

Graded Mutations in Wings of a Stonefly

MORE than two hundred definable variants have been recognized in the wings of the variable stonefly, *Allocapnia pygmaea* Burmeister. Some of them were mentioned in a former paper¹. The three following deviations are new and merit special reference. Figs. 1 and 2 are left and right forewings of the same female, the former nearly normal, the latter highly exceptional; Fig. 3 is the left forewing of another and Fig. 4 that of a third. Left wings are seen from below. In a typical plecopterous forewing (Fig. 1), the radial sector (2) arises directly from the radius (1) by its own radicle; it is separated from the arculus or basal anastomosis (4) by a radial internode (5) and from the median stem (3) by the basimedial

passage (6). The hindwing is characterized, typically but not invariably, by a partial fusion of radial sector and median vein, which leave the arculus by a common mediosectoral pedicel. In *A. pygmaea* these veins issue separately from the arculus on an average of 8 per cent in five hundred hindwings.

In two forewings from a sample of five hundred, there is a perfect mediosectoral pedicel (7) in the right forewing of one (Fig. 2), in the left of the other, so that there is no basimedial passage, no sectoral radicle, and the interractorial cell (8) extends throughout the length of the discal area from the upper division of the arculus to the interractorial crossvein (9). In several instances an adventitious mediosectoral basal crossvein (10) passes from the angle of the sectoral radicle across the intervening space to the median vein (Fig. 3), closing off a basimedial cell (11) from the median basin. This crossvein appears in three states: strong, weak and rudimentary.

In another rare instance (Fig. 4), the sectoral radicle has attained direct nodal fusion with the median radicle (12) and has thus been drawn definitely into the mediosectoral linkage group. If the sectoral radicle faded out of existence or became merged with the arculus, the result would be that shown in Fig. 2.

In conclusion it may be remarked that while these phases are consecutive in form, they are contemporary in incidence, occurring as individual variations.

The Neutrino Theory of Light

SOME time ago I directed attention¹ to some serious difficulties connected with the neutrino theory of light as developed by Jordan and Kronig, namely, (1) the contradiction with the superposition principle especially in the three-dimensional case, and (2) the impossibility of expressing the Bose amplitudes $b(v)$ in terms of Fermi amplitudes $\gamma(v)$. This criticism has met with objections^{2,3}. It has been pointed out that in Jordan's theory the introduction of neutrino-holes is essential and that operators satisfying the Bose commutation rules can be constructed if Dirac's theory of holes is used.

My present purpose is to elucidate some points connected with the operators considered, and to point out that (1) the problem of constructing Bose amplitudes remains unsolved, and (2) new difficulties arise in the theory when the neutrino-holes are introduced.

In a theory working with an indefinite number of particles, the following boundary condition for the wave functional is necessary. *The probability of finding more than N physical particles must tend to zero if $N \rightarrow \infty$.* The boundary conditions in the ordinary theory (physical particles are neutrinos) are thus different from those in the theory of holes (physical particles are neutrino-holes and neutrinos with positive energy). In the ordinary theory, if we put

$$L(v) = \int_{-\infty}^{+\infty} \gamma^+(\alpha) \gamma(v + \alpha) d\alpha, \quad (1)$$

we obtain¹

$$L(v)L^+(\mu) - L^+(\mu)L(v) = 0. \quad (2)$$

In the hole theory, we must introduce a new quantized wave function, $\varphi(\alpha, \epsilon)$, with $\alpha \geq 0$, $\epsilon = \pm 1$, by means of the equations

$$\varphi(\alpha, 1) = \gamma(\alpha); \quad \varphi(\alpha, -1) = \gamma^+(-\alpha); \quad (\alpha \geq 0). \quad (3)$$

The operator (1) transforms⁴ into

$$K(v) = \sum_{\epsilon=0}^{\infty} \int_0^{\infty} \varphi^+(\alpha, \epsilon) \epsilon \varphi(\alpha + v, \epsilon) d\alpha + \int_0^v \varphi(v - \alpha, -1) \varphi(\alpha, 1) d\alpha \quad (v \geq 0), \quad (4)$$

and satisfies the Jordan-Kronig commutation rules

$$K(v)K^+(\mu) - K^+(\mu)K(v) = \mu\delta(\mu - v). \quad (5)$$

Jordan and Kronig put $\sqrt{v} b(v) = K(v)$. But the Bose amplitudes $b(v)$ are defined by their commutation rules only if $b(v)$ and $b^+(v)$ form a complete set of operators, in the sense that any operator commuting with them must be a c -number. This can

only be the case if the parameter v in $b(v)$ includes all the degrees of freedom contained in the arguments of the quantized wave function φ and of the corresponding wave functionals.

This is not the case in Jordan's theory, since $\varphi(v, \epsilon)$ contains, besides v , a new degree of freedom ϵ , corresponding to a replacement of a neutrino by an antineutrino.

From this it follows that: (1) in Jordan's theory the operators $b(v)$ do not form a complete set and are not uniquely determined (we might take for example $\sqrt{v} b(v) = K(v) - K(0)$ as well); and (2) all the probabilities and mean values referring to light quanta depend essentially on the values taken by the ϵ variable.

But a neutrino cannot be distinguished by any physical means from an antineutrino, since according to the very neutrino theory their charge, their mass and their spin are the same and they possess no other physical characteristics. Thus the dependence of the above probabilities on the circumstance whether a particle is a neutrino ($\epsilon = +1$) or an antineutrino ($\epsilon = -1$) constitutes a very serious objection to the neutrino theory. If one remembers that the superposition principle is also violated in this theory and that only neutrinos having strictly parallel momentum—the probability of which is zero—are supposed to contribute to the formation of a light quantum, it is difficult to avoid the conclusion that a consistent neutrino theory of light is impossible.

Number of Fragments of the Pultusk Meteorite

It is generally stated that the remarkable meteorite fall near Pultusk, Poland, on January 30, 1868, consisted of 100,000 stones. Thus Charles P. Olivier in his monograph "Meteors"¹ states that "the famous fall at Pultusk . . . consisted of perhaps 100,000 fragments". Also F. Heide cites in his book² the same number, and places this fall as the highest with regard to number of fragments (in the second place comes the shower at Holbrook, Arizona, on July 19, 1912, with 14,000 fragments). The same number is quoted by various works on astronomy and cosmography.

In 1936 I visited the Mineral Department of the British Museum (Natural History) in London, which contains a beautiful collection of fifty-nine Pultusk meteorites; and in the note placed on the collection I found again the total number "estimated at 100,000". The same value is given also in the guide to the collection of meteorites by Dr. G. T. Prior³.

In spite of this remarkable agreement of data, the high number of 100,000 fragments does not seem to correspond with the facts. Indeed, in the original report on the Pultusk meteorite, published in 1868 by the University of Warsaw⁴, we find that only 400 fragments had been collected, although the total number of stones which reached the ground at the time was greater. On the other hand, the Polish "Cosmography" by J. Jędrzejewicz⁵ estimates the amount of the Pultusk shower at about 1,000 stones,

and the Polish edition of the "History of the Earth" by M. Neumayr* at 3,000 stones.

What is the source of this discrepancy? The original paper of 1868 contains the figure 100,000; this, however, does not refer to the number of fragments of the shower, but only to the result of chemical analysis, which is as follows:

Silicates soluble in HCl	47.014
Silicates insoluble	52.986
	100.000

Therefore it seems to be probable that this total (100 per cent) was erroneously read by someone as hundred thousand and cited as the number of meteoric fragments.

This explanation would account for the enormous figure quoted for the number of fragments stated to have fallen on January 30, 1868, near Pułtusk. As to the real number, I believe that 3,000 stones, as given by Neumayr, may be adopted as the most probable number of fragments.

Points from Foregoing Letters

FROM measurements of the energy of an electron-positron pair, produced by a beta particle of energy 1.1 MV. in a mixture of nitrogen and mercury dimethyl vapour (5 per cent), Dr. F. C. Champion and A. Barber find that there is approximate agreement with the values obtained by Skobelzyn and Stepanowa when beta particles impinged on lead. It appears that the probability of pair production by beta particles of low energy increases rapidly with the atomic number and is large when the energy of the beta particle is of the order $2mc^2$.

The rate of elimination of 0.5-14 millicuries of radon injected into rats is found by Dr. F. Běhounek and F. V. Novák to be half an hour when glucose solution is used as vehicle, and several hours when tungsten emulsion is used as vehicle.

By plotting the logarithm of the rate of diffusion (through rubber) for various gases, against the inverse absolute temperature, R. M. Barrer finds straight line relations. He also gives a table for the energies of activation, calculated from the linear diffusion curves in the case of vulcanized and para rubber, and concludes that only an explanation involving activated diffusion can account for the diffusion increasing approximately with the temperature.

A method for measuring small amounts of gas liberated during certain chemical reactions, using a modified 'Cartesian diver' technique, is described by Dr. K. Linderström-Lang.

D. A. Wright points out that the resistance-temperature curve obtained by Coslett for thin films of indium indicates a transition temperature at about 10°C ., in agreement with Kramer's formula. Thin films of rubidium and caesium, on the other hand, do not behave in accordance with deductions based on Kramer's theory.

The differential cross-section for transition of a Dirac electron between two states of positive energy in a Coulomb field has been calculated by J. O. Jaeger for lead in the case of an incident electron of total energy $3mc^2$ losing energy equivalent to 1.5 and $1.95mc^2$. The theoretical values obtained by Jaeger agree fairly well with the theoretical values calculated by means of Born's approximation except near the short wave limit.

Prof. D. M. Bose reports measurements of the absorption spectra of crystals of neodymium chloride ($\text{NdCl}_3 \cdot 6\text{H}_2\text{O}$), which, he considers, illustrate the six

oxygen atoms grouped octahedrally around a (paramagnetic) neodymium ion. Dr. W. G. Penney and G. J. Kynch point out that the agreement claimed by Spedding and others, between the spacings of the low-lying levels of various rare earth ions, as deduced from absorption spectra measurements and from theoretical considerations of the temperature variation of the magnetic susceptibilities, is probably fortuitous. The magnetic data is not sufficiently detailed to permit accurate determinations of the levels.

A spectrum band in the region 3600-3700 Å. observed when running a high-tension arc between chromium electrodes in a flame of hydrogen burning in air, is attributed by A. G. Gaydon and Dr. R. W. B. Pearse to chromium hydride.

From the intensity of the components in the hyperfine structure of the lines 3944, 3961 and 3993 Å. (observed by absorption) and 6696 and 6699 Å. (observed in emission), D. A. Jackson and Dr. H. Kuhn calculate for aluminium a nuclear spin of $9/2$, which does not agree with the previous value of $5/2$, suggested by Ritschl. The magnetic moment, calculated from Goudamit's formula, is approximately 4 nuclear magnetons.

The results of investigations on the relation between dilution of virus preparations and number of infections caused suggest, according to J. G. Bald and G. E. Briggs, that in the tobacco mosaic group there is an end-to-end aggregation of the virus particles comparable with the 'crystal' structure recently described.

Fruit flies (*Drosophila melanogaster*) treated with fast neutrons from a radium-beryllium source, show, according to Mary Nagai and G. L. Locher, a larger proportion of mutations than untreated flies, as indicated by the sex-linked lethals, which increased $2\frac{1}{2}$ times.

Certain deviations from the ordinary compound interest law of frond increase which have been established for *Lemna minor* grown under constant conditions are described by H. Dickson. These involve a secular variation which takes the form of a wave with a 25-35 day cycle, and superimposed on this a short periodic cycle of 4-6 days. Successive measurements of dry weight also show a secular wave. It is suggested that a social biological effect may be responsible for these growth cycles.

Research Items

Natives of Mount Hagen, Papua

MR. F. E. WILLIAMS, Government anthropologist, Papua, in *Man* of June, records some results of a short visit by aeroplane to the natives of Mount Hagen, the previously unknown tribes first described by Mr. E. W. P. Chinnery in 1934. Information going beyond externals was obtained from Fr. Roes of the Mission of the Society of the Divine Word, who has now resided among them for two years. He estimates that there are now 25,000 natives speaking various dialects of the Mount Hagen language, divided into some twenty tribes, who are again divided into numerous local groups. One of the most remarkable features of the life of these peoples, as well as of the Papuans recently patrolled by Hides and O'Malley, is that they have no villages, but live in scattered homesteads, to some extent grouped together as settlements, something like primitive garden cities. Descent is patrilineal, and marriage patrilocal. Girls marry young, and there is a ceremonial payment. Many households are polygamous. The natives are of strong build and fleshy with somewhat heavy, decided features and a darkish skin. The men mostly wear fine black beards, and the women roll their eyes. Altogether they are a good-looking people, of a caste that is Papuan rather than Melanesian. The main item of dress of the men is an apron of fine netting, black, greasy and soft, which is suspended from the belt, and reaches below the knees. Behind they wear numerous twigs of *Dracena* tucked into the belt. The belt is of stiff bark, up to eight inches and more in width. It is usually plain, but sometimes is decorated with incised geometrical patterns. Thongs of stiff cane may be bound round the belt near the upper and lower margins. To some extent, the belt may have served the purpose of armour. The hair is worn short by boys and youths, but nearly all adults cultivate a fairly long growth, which is tightly encased in bark cloth, bound round the forehead and occiput with a band of the same material. This gives the effect of a well-stuffed globular cushion.

Serbian Gypsy Feast-Days

DR. ALEXANDER PETROVIĆ continues his studies of Serbian gypsies with an account of the feast days they observe (*J. Gypsy Lore Soc.*, Ser. 3, 16, Pt. 3). While the Serbs belong to three religions, Orthodox, Catholic and Mohammedan, the Gypsies are Orthodox and Mohammedan only. As, however, the only mosque is at Nish, the Gypsies of other localities perform for themselves the rites of baptism, marriage and burial. In Bosnia, the Mohammedan clergy hold that the Gypsies were never true Mohammedans. On the other hand, neither are the Orthodox priests pleased with their Gypsy parishioners; but scarcely more satisfactory in his home was the Serbian peasant of the illiterate class up to the beginning of the present century, for he preserved his ancient pre-Christian customs and beliefs. While the Serbs could not carry out a feast without the services of the Gypsies in some capacity or other, the Gypsies, though thus made familiar with them, on conversion

adopted only some of the beliefs and customs of their Orthodox fellow villagers. They considered the feast of Bibi as their greatest religious holy day. Bibi is a disease—cholera. In order to protect their children from being strangled by Bibi, they founded the cult, and propitiate her by celebrating her feast day. She then protects their children from her wrath. This basic idea of a strangler going from house to house is borrowed from the Serbs, who think that the cause of every illness is some living thing that enters a man. Plague and cholera are women dressed entirely in black, who always carry an infant in their arms. It is evident that the Gypsies are beginning to forget the origin of their belief in Bibi. She is for them a Gypsy woman who has babies and likes Gypsies, protecting their children, while she strangles those of the Serbs. Many Gypsies believe that Bibi has appeared to them in their dreams, and this is to them the strongest proof that Bibi really exists. Until some years ago, Bibi's day was celebrated only by a few colonies between Belgrade and Krusevač. Now it is becoming widespread, though confined to Orthodox Gypsies speaking Roman.

Embryonic Monkeys and Man

No complete account of the intra-uterine development of any species of monkey appears to have been published, and therefore the description of the prenatal development of the grey langur, *Simnopithecus priam thersites*, by Prof. W. C. Osman Hill, is of unusual interest (*Spolia Zeylanica*, 20, Pt. 2, 211; 1937). The embryos differ from human embryos very early in showing, as a rule, a double placenta instead of a single one, in possessing 43 instead of 38 body somites, a more slender body form, a longer tail, which persists and grows after the tenth week, and slightly different feet and hands, in which the thumb is rudimentary at the 24.5 mm. stage. On the other hand, resemblances between the development of the monkey and corresponding human stages are shown in the peculiar twist on the long axis of the 9 mm. embryo, the form of the neural tube and cerebral vesicles, the mode of formation of the face and branchial arches, the slight advance in development of fore limb over hind limb, the presence of an umbilical hernia, the disproportionately large head, and large cranium relative to face, the projection of the upper jaw beyond the lower in about one third term embryos, and the presence of a lobule on the pinna. The last character seems to be confined to the family of monkeys to which the genus belongs and to man, for it is not found in the apes, nor in macaques or their relatives. It has, in fact, usually been regarded as a peculiarly human characteristic.

Effect of Pasteurization on the Nutritive Qualities of Milk

THE annual report for 1936 of the National Institute for Research in Dairying, University of Reading, recently issued, contains summaries of two researches carried out at the Institute upon the effect of pasteurization upon the nutritive qualities of milk. In one experiment, shorthorn bull calves when 4-5 days old were grouped in pairs of similar age and

weight, and one of each pair, chosen by lot, received raw, and the other pasteurized, milk until the completion of the experiment twenty-six weeks later. The milk diet was supplemented from the ninth week onwards with a little hay, and from the seventeenth week with a small allowance of crushed oats and flaked maize. Records were kept of the food consumed, the live weight gains, general appearance of the animals and other relevant matters. Eleven pairs completed the experiment, and no material difference could be detected between the two groups. The average daily live-weight gain per head for the calves receiving raw milk were 1.967 lb., for those receiving pasteurized milk 1.969 lb. Another study was on the effect of commercial pasteurization upon the nutritive value of milk. The raw and pasteurized milks were from the same bulk, the experiments being carried out on rats. No marked loss in the value of milk as food which could be attributed to commercial pasteurization could be detected. One fifth of the vitamin C content of raw milk is lost in the course of commercial pasteurization, but this is partly due to exposure to light. Milk exposed in a bottle in the sun for half an hour loses half its original anti-scorbutic properties.

Fossil Insects from Kansas Rocks

CONTRIBUTION No. 16, on Kansas Permian insects, by the late Dr. R. J. Tillyard, appeared in the December issue of the *American Journal of Science* (32, 435-463; 1936). In addition to describing new fossil mayflies, the author discusses the affinities of his group Protohymenoptera. The eminent Russian worker on fossil insects, A. Martynov, and also F. M. Carpenter, of Harvard University, claim that this group is not a separate order apparently ancestral to the Hymenoptera but a subdivision of the fossil order Megasecoptera. Carpenter claimed that Tillyard had misinterpreted the venation, and concluded that any affinities with the Hymenoptera were extremely remote. Tillyard re-examined the subject in this paper and accepted Carpenter's revision of the venation, but reaffirmed his opinion that the Protohymenoptera are ancestral to the Hymenoptera. The fact that a large and complete ovipositor is present in *Asiathohymen*, it is claimed, strengthens this argument. This character, furthermore, argues against Carpenter's contention that the Protohymenoptera are specialized members of the Megasecoptera since none of the latter possessed an ovipositor. The presence of three-segmented tarsi seems to preclude Tillyard's Protohymenoptera being on the direct line of descent of the Hymenoptera, which have five-segmented tarsi. Tillyard argued that since *Asiathohymen* is the most advanced member of the Protohymenoptera, more archaic forms may have possessed tarsi of five segments.

Scottish Copepods

DR. S. G. GIBBONS, who has already studied certain copepods of Scottish seas in some detail, now reports on collections made by the R.R.S. *Explorer* in February-November 1933 on eight cruises covering a large area and including the southern North Sea, the Hebrides and Faroes and round to the Moray Firth ("*Calanus finmarchicus* and other Copepods in Scottish Waters in 1933". Fishery Board for Scotland. Scientific Investigations 1936, No. II). Except for two large isolated patches at the surface in May and June, the bulk of the *Calanus* population (later

copepodid and adult stages only being considered) were taken in the mid-water and bottom nets and few were in the surface layer. From February until July they were mostly in mid-water; from August onwards they were in the deepest layer. This indicates a general sinking towards the end of the year. There is conspicuous vertical movement, and the figures show a maximum diurnal migration which takes place at those seasons when the hours of darkness are longest, whilst in July when the light is strong the difference is less marked. As in previous years, *Calanus* proved the dominant plankton organism throughout the year, their greatest abundance occurring in June in the Faroe Shetland Channel region, and the least in the North Sea in November. Among the other copepods mentioned is *Anomalocera patersoni*, the 'blue feed', well known as important herring food, which occurs in numbers in certain areas in May and June. It is noteworthy that, in the chart showing its abundance together with *Calanus*, it should be usually more abundant than that species when it occurs. Although nothing is said to this effect, it is probably because *Anomalocera* is eating *Calanus*, for it is a voracious copepod feeder.

Feeding Habits in Pleuronectidae

THE relationship between the structure of the brain and the feeding habits of the Pleuronectidae has been studied by H. Muir Evans (*Proc. Roy. Soc., B*, May 1937). The same author has previously shown a relationship between the structure of the medulla oblongata and the feeding habits in cyprinoids, alupeids and gadoids. In the present work, the investigation is extended to include the fore-brain, mid-brain and infundibulum. Four groups can be recognized: (1) typified by the sole, a purely bottom, night feeder; (2) typified by the plaice, which is also a bottom feeder but utilizes sight, taste and smell; (3) typified by the turbot, which is predatory and feeds by sight; and (4) typified by the halibut, also predatory and feeding by sight. The fourth group is distinguished from the third by the deep dorso-ventral extension of the olfactory lobes and by a different arrangement of the tubules of the pituitary gland.

A Disease of Hawthorn

A SHORT paper by Messrs. W. J. Dowson and W. A. R. Dillon Weston (*Gard. Chron.*, 426, June 19, 1937) directs the attention of plant pathologists to a brown rot of the hawthorn. The malady, which is fairly widely distributed in East Anglia, is caused by the fungus *Sclerotinia orotagi*. The conidial stage only has yet been found in Great Britain, but the ascigerous condition has been known for many years in Germany and the United States. Similar diseases appear on the medlar and quince, but are caused by different species of *Sclerotinia* from that which attacks the hawthorn. Symptoms are a browning of the young shoots, the dead leaves of which often bear a sweetly-scented powdery grey mould of conidia. The disease may be more widespread than is reported by the present paper, and appears to be sufficiently destructive to mar the beauty of a quick-thorn hedge.

Gold Deposits of the Canadian Shield

A REVIEW of the geological relations of some of the chief gold deposits of the Canadian Shield is presented by E. L. Bruce in a paper read at the New York Meeting of the American Institute of Mining

and Metallurgical Engineers (*Technical Publication* No. 807; 1937). Summaries are given of the Beattie and Sisoo mines of Quebec, of the mines of the Porcupine and Kirkland Lake area, and of the Howey and other mines of north-west Ontario. It is shown that there are few places in which a genetic relationship between ore-bearing solutions and neighbouring igneous rocks can be satisfactorily established. In some places where such relationships have been assumed, later investigation has shown that the igneous rocks are very much older. In deposits like those of Porcupine and Kirkland Lake, it seems likely that the solutions that formed the veins were derived from a magma far below the present surface and that the veins are localized by structural factors. The fact that contacts between igneous rocks and the rocks invaded are structurally favourable for the development of zones of fracturing, in some deposits at least, explains the occurrence of gold-bearing veins near intrusive bodies.

Formation of Submarine Canyons

IN recent years, there has been much discussion of the various hypotheses suggested to explain the formation of submarine canyons and gorges. The only hypothesis to which there are no serious objections is that proposed by Daly. During the low sea-levels of the Pleistocene glaciations, mud was stirred up by wave action on the shallowing continental shelves. In this way, a suspension was formed with a higher specific gravity than that of clear seawater. The 'heavy' liquid flowed down the continental slope, as submarine currents which developed runs in the soft bottom deposits and gradually deepened them into gorges. This theory, though superficially seeming to be improbable, has been greatly strengthened by experiments carried out at Leyden by Ph. H. Kuenen (*Leidsche Geol. Med.*, (2), 8, 327-351; 1937). The results prove that a suspension will flow down a slope without being much diluted by mixing with the adjacent clear water, and that such a flow will concentrate in slight depressions in the surface. Quantitative data and comparison with natural slopes show that the velocity of the actual submarine currents should be somewhat lower than that of large rivers, but increasing as it proceeds and picks up more sediment. At the lower end the suspension gains six times the effective density with which it began and two or three times the velocity, and at this stage the load of sediment being carried is that of the most muddy major rivers. Though the data are rough, they show that no preposterous assumptions are involved in accounting for such submarine canyons as those of the Georges Bank. It is of special interest to note that an 8 mm. film of about 20 metres length, illustrating the experiments, can be obtained at the price of 8 guilders from the Rijksmuseum van Geologie at Leyden.

A New Type of Threaded Connexion for Oil Well Casing

At a meeting of the Institution of Petroleum Technologists on May 4, Mr. W. M. Frame described a new type of threaded connexion for use on oil well casing. Casing having such connexions is known as 'extreme line casing' and is being used successfully in a number of the United States oil fields. The joint consists simply of an upset, threaded pin end and an upset, threaded box end without any coupling. A shoulder is provided on the pin end to avoid any abrupt change of contour, and the outer surface is

turned and the inner bored to give more accurate joint dimensions than are normally obtainable. The advantages claimed for this type of joint over the normal V-threaded type are that it is stronger and has a higher resistance to leakage and accidental drainage, that the external joint diameter is smaller and has a stream-lined contour both inside and out. Experience has shown that a great saving of time in running and pulling can be effected with this 'extreme line casing' as compared with collared casing.

A West Indian Hurricane

AN account was given by Mr. C. S. Durst, at the meeting of the Royal Meteorological Society on May 26, of a case that occurred in September 1936 of a West Indian hurricane which recurved into middle latitudes towards the far side of the Atlantic and crossed over almost to the Irish coast without losing its tropical character of a mass of revolving tropical air. The recurve took place at about lat. 30° N., long. 61° W., and the track of the storm was then an almost straight one to the south-west of Ireland. As the storm approached the polar front, which lay at about lat. 45° N., a new depression developed on that front and became intense, and to this development is attributed a great increase in the speed of travel of the tropical storm. When centred at about lat. 43° N. and long. 39° W., its continued tropical character was well shown by the existence of a northerly wind of nearly gale force of which the temperature was 74° a short distance behind the centre. The author was unable to find any previous case of this kind of a persistent revolving tropical vortex within the warm sector of another depression farther to the north. He attributed the abnormal features in this case to the fact that the encounter between the tropical storm and the polar front took place in mid-ocean, and to the fact that a very shallow disturbance already existed on the polar front at that point. It is more usual for tropical storms to reach the coast of America and to have greatly diminished in intensity by the time that they encounter the polar front, and for their tropical characteristics to be lost in the temperate depression which results.

Passivity of Iron

EXPERIMENTS by W. H. Cone and H. V. Tarter (*J. Amer. Chem. Soc.*, 59, 937; 1937) show that iron is passive in solutions of chromic acid at all concentrations. If the solution also contains sulphuric acid or other activating electrolytes such as phosphoric acid and sodium sulphate, the iron under reduced pressure becomes active, but in pure chromic acid solutions iron does not become activated by reduction of pressure. An atmosphere of hydrogen causes iron to be active in a chromic acid-electrolyte solution. Oxides of iron were found to be soluble in chromic acid solutions, and oxide-covered wires could be made active by a reduction of pressure. This makes it doubtful whether an oxide layer is an essential factor for passivation, as has been asserted, and an adsorbed film of oxygen or a "two dimensional compound" of iron and oxygen as the primary cause of passivity is suggested. Definite oxides may be formed afterwards, particularly in the case of anodic passivation, but such oxides are readily soluble in the acidic solutions used by the authors.

Transmission of Excitation in Living Material

ON Thursday, June 3, at the Royal Society, Dr. C. F. A. Pantin opened a discussion organized by Prof. A. V. Hill on "The Transmission of Excitation in Living Material", which was largely devoted to the consideration of the rival merits of electrical and chemical theories of conduction.

The electrical theory, which has been worked out mainly in connexion with the nerves of vertebrates, is briefly as follows. We know that conducting tissues may be excited at the cathode by an applied electric current, and we also know that the propagated wave is invariably associated with an electric disturbance which is in such a sense that the current flowing between the active and the inactive regions of the tissue has the cathode on the inactive part, and is hence in the direction which tends to excite it. Thus it is clear that if the disturbance is intense enough, the inactive region in front of the wave must be raised to activity, thereby achieving propagation. Whether in fact this is the mechanism therefore rests upon the measurement of the adequacy of the electrical disturbance to excite the region in front of the wave.

This study was presented by A. L. Hodgkin (Cambridge), working on frog's nerve in which the propagation was blocked by the application of pressure or by freezing. Though the impulse is not able to traverse the block, yet the electrical current spreads out into the inactive region and produces there a considerable exciting effect, for, when the shock setting up the impulse is followed by a second shock applied this time to the inactive region just beyond the block, and so timed that it coincides with the electrical disturbance due to the blocked impulse, it is found that the second shock can be effective at only 10 per cent of the intensity necessary when applied alone. The excitability thus measured is found to follow a time course nearly identical with that of the electrical wave from the blocked impulse. It is clear that if at some distance from the disturbance the excitability is raised to 90 per cent threshold, at the active region itself the current will be fully adequate. Thus the electrical theory is established for conduction in frog's nerve.

But the adequacy thus shown for a full-grown impulse will not apply to the very small impulse arising from the area under the cathode of an external stimulating circuit. It is clear that a stimulus, to be effective, must not only excite the tissue at a point, but also must nurse the new-born impulse until it has reached a size adequate to propagate on its own.

The results of a mathematical development of this aspect were presented by W. A. H. Rushton (Cambridge), who pointed out that, in spite of shortcomings due to over-simplification, it is possible to describe quantitatively the whole range of excitability measurements both spatial and temporal, including some observations hitherto unexplained, with only two arbitrary constants.

Now in the intact organism, nerve-muscle activity is carried out by impulses following each other in rapid succession, hence the electrical generation of repetitive impulses from continuous currents is of interest. A. Monnier (Paris) has found that excised nerves and muscles in solutions of low calcium ion

content respond to prolonged continuous currents with prolonged rhythmic discharges. The bearing of this upon the mode of origin of central nervous rhythms was strongly indicated by B. H. C. Matthews (Cambridge) from oscillograph records of single motoneurons. When these cells are provoked to reflex activity by sensory stimulation, in addition to the quick potential change associated with each impulse there are slowly developed changes localized somewhere in the spinal cord, apparently produced by the cumulative effect of the sensory impulses, and acting like the prolonged currents in Monnier's experiments. This similarity has been further confirmed by passing a prolonged current in at the nerve and out at the cord, which, even in the absence of sensory stimulation, produced repetitive impulses of reflex character.

Though these experiments suggest that electrical considerations are sufficient to explain the passage of an impulse from one cell to another, there is quite other evidence, primarily pharmacological, which shows that the liberation of a specific chemical substance in relation to the cell junction may be of great importance.

Adrenalin has long been known to produce, when injected, the same general effects as widespread sympathetic stimulation, and it is now recognized that sympathetic nerves act by liberating adrenalin (or something very like it) in intimate relation to the cells of the organ supplied. Later, a similar state of affairs was found in connexion with the parasympathetic nerve endings, but the specific chemical, acetyl-choline is rapidly inactivated by an enzyme normally present and hence cannot be obtained unless the enzyme is inhibited by eserine. Chemical transmission was thus established in conduction between cells in two important classes, and the question arose as to whether some chemical was invariably necessary for such conduction. In particular, the cases of nerve-voluntary muscle, sympathetic ganglion and central nervous system are receiving consideration, but the possibility of a similar chemical counterpart of transmission down the nerve fibre itself is not overlooked.

A. von Muralt (Bern), realizing that any liberation of acetyl-choline during nerve transmission must be almost instantaneously reversible, adopted the following method to 'fix' the chemical liberated by a single impulse. The stimulated nerve together with an unstimulated control were shot instantaneously into liquid air, withdrawn, and ground to powder in solid carbon dioxide and then extracted and tested pharmacologically for acetyl-choline. It was found that the stimulated nerve contained about twice as much as did the control, but as was brought out in discussion with Prof. J. H. Gaddum, this was possibly due to the effect of the applied current (as in Gaddum's own experiments) for the results were more pronounced with prolonged currents, and the 'resting' control was probably excited by contact with the liquid air.

G. L. Brown (Hampstead), continuing the work of Dale and his other colleagues, showed that when an impulse passes from nerve to muscle, not only is acetyl-choline liberated in circumstances strictly

imited to the passage of the impulse, but also that the injection of it suddenly into an artery in close relation to the muscle gives rise to a twitch very similar both from mechanical and from electrical records to that produced on nerve stimulation.

F. Buchta (Copenhagen) has made a more minute study of the structures involved in this transmission. Working with single muscle fibres from the lizard, he measured the resting and active potentials on the surface of the muscle and the nerve-muscle junction. There is a resting potential of some 50 mV. between junction and fibre, and this difference is reversibly reduced to zero by the drug curare, which simultaneously produces a reversible nerve-muscle paralysis.

Z. N. Bacq (Liège) treated from a much wider zoological aspect the question of chemical transmission, and showed that, though acetyl-choline may be regarded as transmitter over a great range, yet this substance is not present in the Protochordates, the Crustacea, or the Coelenterates.

J. O. Eccles (Oxford) considered the application to ganglion and central nervous system. He presented evidence for two transmitters, one rapid, and apparently related to the electrical effect, the second slower and probably related to acetyl-choline.

This same duality was advocated by C. F. A. Pantin (Cambridge) in his opening communication. His own work on sea anemones and crabs shows that facilitation at the nerve-muscle junction depends upon both the number and the frequency of impulses arriving there. A chemical transmitter is suggested because the time relations of the decay of facilitation

are much longer than those of electrical effects, and are not dependant upon ions as are the electrical phenomena. On the other hand, the accumulation of facilitating chemical is never sufficient to set up repetitive impulses on its own account, nor are the ionic changes which increase facilitation capable of allowing a first impulse to pass; it seems that in these systems it is necessary to have the electrical change associated with the present impulse as well as the chemical facilitation resulting from a previous impulse. He also pointed out that the study of comparative physiology is rich in examples of the same end being achieved by different means, and of the same means being employed to different ends, or to no end at all. The fact that a certain chemical has important function in one tissue and that it is also present in another tissue, cannot be used as indicating that it has any biological significance in the second case.

Prof. E. D. Adrian, starting the open discussion, was also of the opinion that both electrical and chemical conditions are involved in transmission. He pointed out, however, that the secretion of molecules so strongly polar as those of acetyl-choline may involve quite considerable potential changes, while on the other hand the diffusibility of acetyl-choline through lipoids makes this ion of importance in the passage of electricity through cell walls. It is therefore possible that some of the phenomena variously considered as electrical or chemical may in fact be merely two aspects of the same process.

W. A. H. RUSHTON.

The Individuality of Gliadin

By Prof. A. G. Kuhlmann, Research Institute of the Baking Industry, Moscow

THE principal proteins of wheat are, as is well known, glutenin and gliadin. These proteins, upon the interaction of wheat flour with water, form the so-called gluten, the quality and quantity of which is of such great significance in the baking of bread, in the manufacture of macaroni, noodles and similar products. In the numerous works devoted to the proteins of wheat, a great deal of attention is paid to the question of the individuality of glutenin and gliadin.

Considering gluten to be a natural high polymer, we must come to the conclusion that it represents a complex of proteins, forming micelles of various length. Such a conclusion has been fully confirmed by an investigation which I conducted in my laboratory, which showed as well that the longest and most stable micelles are those of glutenin. Gliadin consists of shorter micelles, which are less stably built and more flocculent than those of glutenin.

According to the literature, the gliadin of wheat is best extracted by a 70 per cent solution of ethyl alcohol. A study of the influence of the concentration of ethyl alcohol on the peptization of the proteins of gluten carried out in my laboratory gave the following picture (Fig. 1). In one series of experiments, samples of one and the same gluten were treated with alcohol-water solutions. The

experiments were repeated, this time a given sample of gluten being treated with alcohol solutions of increasing concentration (alcohol of higher concentration being used only after complete extraction with alcohol of the preceding lower concentration).

Fig. 1.

Results of these experiments are shown in Fig. 2. The data of both these series of experiments are in good agreement with each other and show that maximum peptization occurs with alcohol having a concentration of about 40 per cent. The

investigation of several kinds of gluten gave an analogous picture.

When gluten is treated with alcohol of low concentration (up to 30 per cent C_2H_5OH) it retains its cohesive properties and changes only slightly in its external appearance. Upon treatment with 40 per cent alcohol, it is greatly altered; it loses its cohesive properties and begins to disintegrate into separate particles. The supernatant liquid becomes turbid and viscous.

It is a striking fact that peptization of gluten by alcohol of various concentrations falls considerably more sharply after reaching a definite maximum, in the case illustrated by Fig. 2 than that by Fig. 1. This can be accounted for by the presence in gluten of a less highly aggregated and more easily peptizable fraction the solubility of which reaches a maximum with concentrations of alcohol of about 40 per cent. This fraction, through interaction with the more highly aggregated and less soluble fraction of gluten by means of absorption, acts as a peptizer of the latter. It also conditions the stability of the sol obtained. This fraction, when separate samples of gluten are extracted by different concentrations of alcohol (Fig. 1), asserts its action even at high

Fig. 2.

concentrations; while when one and the same sample is extracted by alcohol of different concentrations, the alcohol solutions containing more than 40 per cent C_2H_5OH , devoid of this less highly aggregated fraction of gluten due to its solution by the alcohol solutions of lesser concentrations, show a sharp decrease in peptizing properties (Fig. 2).

A study of the peptization of the proteins of gluten as a tricomponent system, sol of gluten - alcohol - water, using the method of the triangular diagram of Gibbs, was also carried out in my laboratory on twelve specimens of wheat. In general, they all gave analogous results. A typical example is shown in Fig. 3 (a). Isopeptides (lines connecting the points of equal quantities of peptized colloids) clearly show a definite maximum of peptization at a definite concentration of alcohol (40-50 per cent). If isoprotein sections (lines I, II, III) parallel to the side BC and connecting points of equal quantities of protein are drawn, then the above-mentioned maximum is seen still more clearly (Fig. 3 (b)).

If proteins are extracted with 40 and 70 per cent alcohol-water solutions from separate samples

of a given specimen of gluten, then we obtain two products, different from each other with respect to their behaviour towards water (swelling and hydration). Thus the protein fraction extracted with 40 per cent alcohol from the gluten of the wheat *Lutescens* 0329 imbibes 1.63 gm. of water (calculated on the basis of 1 gm. of dry substance), while gliadin (that is, the fraction extracted from that same sample of gluten with 70 per cent alcohol) imbibes 1.83 gm. The corresponding fractions extracted from the glue

Fig. 3.

of the wheat *Ferrugineum* H 622 gave a still more distinct picture: here gliadin imbibed 1.08 gm. of water while the '40 per cent-fraction' imbibed 0.91 gm. The gliadin of that wheat increased its volume by 15 per cent on swelling, while the '40 per cent-fraction' increased by 135 per cent.

The above data, as well as other observations noted in my laboratory, give me reason to maintain that the gliadin of wheat is not a chemical individual. It represents an adsorption complex of at least two fractions, which I name α - and β -gliadin. In its properties (swelling, peptization etc.) β -gliadin approaches glutenin. β -gliadin dissolves as a result of interaction by means of adsorption with the more easily peptizable fraction α -gliadin, which forms the main mass of Osborne gliadin.

Fig. 4.

In the light of this work, the distribution of proteins of the various fractions of gluten according to the length of their micelles may be represented schematically as in Fig. 4.

Research in this field is being continued.

Intellectual Co-operation and International Science

A JOINT meeting of the Executive Committee of the International Council of Scientific Unions and of the Scientific Experts Committee of the International Organization of Intellectual Co-operation was held on July 9-10, at the International Institute of Intellectual Co-operation, in Paris.

Representing the Executive Committee of the Council were: Prof. C. Fabry, chairman of the Council; Prof. H. R. Kruyt, vice-president; Prof. S. B. Némec; Prof. F. J. M. Stratton, general secretary of the Council; E. Esclançon, representing the International Union of Astronomy; Jean Gérard, representing the International Union of Chemistry; General Perrier and Brigadier H. St. J. L. Winterbotham, representing the International Union of Geodesy and Geophysics; General Bourgeois and L. J. Voute, representing the International Union of Geography; Profs. Abraham and A. Cotton, representing the International Union of Physics; and Dr. M. J. Sirks, representing the International Union of Biological Sciences. The Committee of Scientific Experts included: Prof. Cabrera, chairman of the Committee and professor of theoretical physics at the University of Madrid; Prof. Bialobrzewski, professor of theoretical physics in the University of Warsaw; Prof. F. A. E. Crew, director of the Institute of Genetics at the University of Edinburgh; Prof. P. Langevin, professor of experimental physics in the Collège de France; Prof. Ch. Maurain, dean of the Faculty of Sciences of the University of Paris; Prof. Harry M. Miller, professor of zoology in Saint Louis University; Prof. M. Plancherel, professor of mathematics in the Polytechnic Federal School of Zurich; Prof. A. A. J. de Sigmund, professor of agricultural chemistry in the Palatin Joseph University of Technical and Economical Sciences, Budapest; and Prof. E. Späth, rector of the University of Vienna.

This meeting is the result of several years negotiations between the International Council of Scientific Unions and the International Organization of Intellectual Co-operation, the outcome of which was the approval by the assemblies of the two organizations of the draft agreement prepared by a joint committee of representatives of the Council of Scientific Unions and of the International Committee on Intellectual Co-operation.

The agreement lays down in detail the manner in which the two institutions are to collaborate. The

International Council of Scientific Unions will henceforward act as the advisory body to the Intellectual Co-operation Organization on questions of a scientific character, while the latter will be consulted by the Council on all international matters concerning the organization of scientific work. The executive organs of the Intellectual Co-operation Organization will provide the secretariat for the committees to be appointed by the Council, the president of which will *ex officio* attend plenary meetings of the Committee on Intellectual Co-operation at which the sciences are discussed; a representative of the Intellectual Co-operation Organization will take part in the meetings of the Executive Committee of the Council.

One of the aims of the meeting of July 9-10 was the signing of this agreement by the presidents of the two organizations, Prof. Gilbert Murray and Prof. C. Fabry. It also dealt with a number of other questions, among which are: the analysis of the scientific programme of the Organization of Intellectual Co-operation, that is, co-ordination in the matter of scientific research (financial aid, collaboration with the scientific unions for the preparation of small co-ordinating committees, publication of reports on the progress made in each branch of science); scientific bibliographies (transcription of the titles and the names of authors of scientific works written in a language that does not use Roman characters, and compilation of a bibliography of scientific works published in such languages); 'scientific conversations' the first of which will deal with "the general consequences of deep alterations that have taken place in physics concerning the principles of the explanation of the natural phenomena", etc. . . .

The Committee has also studied the programme and methods of the International Council of Scientific Unions and examined several new proposals received by the Organization of Intellectual Co-operation, among which are the publication of old scientific manuscripts and the question of the co-ordination of work in the study of physical constants.

It is necessary to emphasize the importance of the signing of the agreement by the presidents of the two organizations. It marks the beginning of a practical collaboration removing all possibility of overlapping, and having as a result the development of a definite programme.

New Chemistry Laboratories at Birmingham

THE new A. E. Hills Laboratories, which form a most valuable extension of the Department of Chemistry in the University of Birmingham, were formally opened by the donor (Mr. A. E. Hills) on July 7. The pro-chancellor (Mr. Walter Barrow) expressed the gratitude of the University to Mr. Hills for his generosity in giving £50,000 to build the laboratories, as well as a further gift of £25,000 for postgraduate scholarships. Benefactions by Birmingham donors have provided a further £7,700 for equipment (including £4,200 from Cadbury Bros. and £2,000 from W. Canning and Co.)

The opening address was given by Sir Frederick Gowland Hopkins, who remarked that every encouragement given to chemistry increases the possibility of discoveries of universal value. The thoughts of physicists and that of chemists, which have been separate, are coming nearer together, and the help which chemistry has given to physics in the past is to-day being handsomely repaid; though there is still an inherent distinction between the modes of thought of the chemist and physicist which is of mutual advantage in their collaboration.

Chemistry is also becoming more serviceable to medicine and all the biological sciences. The psychiatrist is now coming to the chemist for help. Many forms of mental disorder appear to arise from disturbances of metabolism which are revealed by chemical studies, and there is hope that methods of treatment may be found to correct the errors so discovered. If only some forms of insanity can be cured, it would be at least a partial solution of one of the most painful human problems. "Extending this idea, may we not believe that even the psychologist will have to pay attention to chemistry? So intimately interwoven are the activities of mind and body that no one can deny that the psychology of the individual is greatly affected by the hormonal balance which is part of his physical constitution; and hormones owe their specific influence in the body to particular aspects of their molecular structure". Chemistry in fact is ubiquitous, though it required the Great War to make Great Britain realize the truth of Disraeli's dictum that the prosperity of the chemical industry is the best index of the prosperity of the country as a whole.

The distinction between pure and applied science is becoming less real, and it is probable that never before has organic chemistry shown more possibility of continued development. How remarkable in kind the development of organic chemistry has been in its apparently static time. The product of a pictorial, or even artistic rather than mathematical type of intellect, the evolution of the idea of molecular structure was something new and distinct, and the verification by modern physical methods of the conclusions reached is indeed remarkable. Organic

chemistry in approaching physics is becoming more dynamic and more subtle.

Biochemistry is a borderland subject (not a hybrid because it is certainly not infertile), and borderland workers usually find work not found by the cultivators of either of the contiguous regions. Intellectual trust and sympathy between two departments may be very fertile. Biochemistry is the study of chemical dynamics as exhibited in life, and requires a knowledge of the physical properties and molecular structure of the substances which play an essential part in the constitution of living systems. Its special endeavour must be to follow so far as possible the function and fate of each significant constituent amid the multitudinous reactions which underlie the manifestations of life, and to explore the mechanisms which control those reactions. For this work, biochemistry is developing its own technique, and its progress though difficult is real. While immersed in problems so different in kind, it is almost impossible for the specialized biochemist to acquire the knowledge and experience, or the mode of thought and intuitions of the accomplished organic chemist, in determining molecular structure and in the difficult art of synthesis. Even the best biochemist must remain an amateur in organic chemistry. There never was a case in which progress could be better secured by a wise division of labour. Recently organic chemists have been examining the structures of natural products with marked success.

Sir Frederick concluded with a eulogy of the work of the Birmingham University School of Chemistry, referring in particular to the synthesis of vitamin C, the commercial manufacture of which means that no case of scurvy need in future remain uncured.

Standardization of Physical Units

IN a paper by Lyman J. Briggs, director of the National Bureau of Standards at Washington, which appeared in the January issue of the *Journal of the Franklin Institute*, some of the present-day problems in connexion with securing international uniformity in standards are discussed.

The British inch, derived directly from the imperial yard, is about four parts in a million shorter than the United States unit. But if we use the conversion factor so that one inch equals 25.4 millimetres exactly, then the new value of the inch would fall midway between the British and the United States inch. The Bureau of Standards has definitely proposed that this be done. The change would not affect industry in the slightest because it falls well within the tolerances in industrial measurements. This conversion factor, one inch equals 25.4 mm., has recently been adopted for industrial purposes by standardizing groups in fifteen countries including both England and the United States.

In the field of electricity, the tools of measurement now depend on national standardizing laboratories. The maintenance of units is made possible on a world-wide basis by the rise of the great national standardizing laboratories, especially in Germany, Great Britain and the United States. The revision of the units is under way at the present time. But as the present units are more than sufficiently accurate for

industrial use, the changes made will only affect laboratories making very precise measurements. The change will become effective on January 1, 1948. The present 'international' units of the ampere, ohm and volt will be respectively 0.9999, 1.0005 and 1.0004 of the new (absolute) ampere, ohm and volt respectively.

The present standards for use in photometry are either flame standards or carbon filament lamps giving light of a yellowish colour, and there is a general agreement as to a method regarding a method of passing over to lamps giving 'whiter' light. The German-speaking countries also never accepted the old 'international candle' but use their own unit, the Hefner, which is only nine tenths of it. Now the Bureau of Standards has determined the behaviour of the normal eye in terms of 'factors of luminosity' which have been internationally agreed as a basis has been fixed for measuring lights of all colour provided we have some kind of standard as starting point. We have still to agree upon the photometric scale for the brightness of the primary standard. The Bureau of Standards has recently suggested that the old 'international candle' be abandoned and that a slightly different unit be fixed by taking the round value of 60 candles per sq. cm. instead of the old value of 58.9, as the brightness of the blackbody radiator at the platinum point.

Science News a Century Ago

The Engineering Branch of the Royal Navy

ON July 19, 1836, an Order in Council was promulgated which for the first time granted permanent rank to engineers serving in the Navy and laid down the regulations for the training and employment of engineers. The Order in Council began: "Having had under our serious consideration the situation of the Engineers of Your Majesty's steam vessels, and being of opinion that it is necessary to place this description of officers on a permanent footing, in the same manner as the Gunners Boatswains and Carpenters in Your Majesty's Navy, with such rank and pay as appears to be fitting for persons charged with the performance of such important and responsible duties, we beg leave most humbly to entrust for Your Majesty's most gracious consideration and approval the following regulations. . . ." The engineers were to be appointed in the same manner as other warrant officers; they were to rank next below carpenters; they were to be distributed into three classes and they were to be allowed to retire upon superannuation upon the scale laid down for warrant officers in 1826. The pay of a first-class engineer was to be £9 12s. a month, and sixpence a day for each apprentice or boy that may be placed under his instruction; the pay of a second class engineer was to be £8 16s. a month and that of a third class was to be £4 18s. a month. On entry into the service engineers had to pass an examination before the Chief Engineer and Inspector of Machinery or such other officer as might be appointed for that service.

The Order concluded with: "And with a view of encouraging the education of youths in Your Majesty's Service for Engineers, we beg leave further most humbly to propose that Your Majesty will be graciously pleased to establish four classes of Apprentices or Engineers' Boys, for the service of Your Majesty's steam vessels, with the following rates of pay: 1st Class, £1 14s.; 2nd Class, £1 6s.; 3rd Class, £1 3s.; 4th Class, 14s. 6d. a month."

Launch of S.S. *Great Western*

ON July 19, 1837, the S.S. *Great Western*—the *Queen Mary* of her day—was launched at Bristol. Designed by Isambard Kingdom Brunel and built by Patterson for the Great Western Steamship Company, which had been formed at Brunel's suggestion for connecting Bristol with New York, she was the largest vessel constructed up to the time she was launched. She was 236 ft. long, 35½ ft. beam, 59 ft. wide over the paddle boxes and of 1,320 tons. "Her scantling," wrote one author, "is equal in size to that of our line of battleships, it is filled in solid, caulked within and without up to the first futtock heads before planking, and all above this height is of English oak. The flooring is of immense length, each floor overrunning the other; they are strongly dowelled and bolted in pairs first and also together by 1½ in. bars of 24 ft. in length, driven in parallel rows, scarfing about 4 ft. She is trussed in the firmest and closest manner by iron and wooden diagonal and also shelf pieces, these including all the upper works, are fastened with screws and nuts to an immense extent." After being launched, the ship was towed to the Thames to have her engines fitted. She made her first voyage to America in April 1838.

Meteorology in the United States

AT the fifty-fourth quarterly meeting of the Franklin Institute of Philadelphia held on July 20, 1837, the report submitted contained the following statement: "Whereas, a considerable number of members of this Institute, in conjunction with members of the Philosophical Society, have recently devoted much time to the observations of the phenomena accompanying the various conditions of the atmosphere, with a view to ascertain the general laws by which the changes of weather are governed; and the belief is confidently entertained, that a continuance of these observations, and their extension over the widely spread territory of the United States, will enable us to determine many general facts of a highly important and useful character, therefore, Resolved, that the Joint Committee of the American Philosophical Society and the Franklin Institute be, and are hereby authorized, on the part of this Institution, to memorialize Congress for the purpose of obtaining the national aid in furtherance of this interesting object."

University Events

ABERDEEN.—The following degrees of D.Sc. have recently been awarded: E. M. Dodds, for a thesis entitled "Researches on the Internal Combustion Engine and its Fuels"; Dr. A. W. Downie, for a thesis entitled "Studies on Immunity to the Pneumococcus"; Dr. D. S. Raitt, for a thesis entitled "Stock Replenishment, Fishing Intensity, Yield Prediction and Ancillary Problems in relation to the Haddock Stocks of the North-East Atlantic"; Dr. H. E. Shortt, for a thesis entitled "Life-history and Morphology of *Babesia canis* in the Dog-Tick *Rhipicephalus sanguineus*".

The honorary degree of LL.D. has been conferred on Prof. T. Shennan, emeritus professor of pathology in the University.

BELFAST.—The degree of D.Sc. has recently been conferred on the following: Prof. W. A. Osborne (*honoris causa*), M. J. Lynn (botany) and R. H. Sloane (physics).

CAMBRIDGE.—The following University appointments have recently been made: Dr. O. M. B. Bulman, lecturer in paleozoology; Dr. J. K. S. St. Joseph, demonstrator in geology; M. Black, demonstrator in geology; J. D. Boyd, lecturer in anatomy; Dr. W. A. H. Rushton, lecturer in physiology; S. J. R. Reynolds and C. D. P. Jones, demonstrators in anatomy; A. L. Hodgkin, demonstrator in physiology; and Dr. G. N. Myers, demonstrator in pharmacology.

A. M. Barry has been appointed to a Frank Edward Elmore studentship as from October 1.

The Frank Smart prizes have been awarded to B. G. Wilkinson, Downing College (botany); M. G. M. Pryor, Trinity College (zoology).

Applications are invited for the Gwyneth Pretty studentship, the holder of which shall devote himself to original research in the etiology, pathology and treatment of disease, with particular but not exclusive reference to those diseases which cripple or disable in childhood or early life. The studentship is of the annual value of £200 and is tenable for three years. Further information can be obtained from Prof. H. R. Dean, Department of Pathology.

Societies and Academies

Edinburgh

Royal Society, Edinburgh, June 7, 1937.

H. S. TAYLOR: Heavy hydrogen in scientific research (Bruce-Preller Lecture). Heavy hydrogen has led to interesting developments in theoretical and experimental aspects of reaction kinetics, especially in the fields of catalysis and photochemistry. Problems of molecular structure involving all types of spectral analyses of deuterium-containing compounds have also been solved. The biological and astronomical aspects of the problem were discussed, and the important role of deuterons, at high voltages, in the production of artificially radioactive elements and isotopes of known elements, particularly in the field of radiotherapy, was indicated.

A. O. ATKIN: Studies in practical mathematics. (2) The evaluation of the latent roots and latent vectors of a matrix. The paper develops and exemplifies a method, based on the repeated transformation of a vector, for finding all the roots and characteristic vectors of the secular equation and more general determinantal equations. By a simple auxiliary process a few poor or moderate first approximations are shown to be capable of yielding second and later approximations of high accuracy. Numerical examples are used to illustrate the routine of computation, which is well adapted to modern machines. F. A. E. CREW and CH. AUMBACH: 'Spheroidal': a mutant in *Drosophila funebris* affecting egg size and shape, and fecundity. 'Spheroidal' eggs are broader and shorter than normal, with greater variability in both dimensions and also in the shape index. These differences, as well as the abnormal curves of regression of length on width and of volume on length, suggest fundamental deviations from the normal processes concerned in egg development. 'Spheroidal' females are remarkably infecund, and differ from normal in respect of the curve of laying performance from day to day.

FRANCIS GREENSHIELDS: Studies in the cytology of parthenogenetic reproduction of Hymenoptera Symphyta. (1) Chromosome number and individuality in three arrhenotokous species. The complement of 0 chromosomes in the male germ-track of three arrhenotokous species of Hymenoptera Symphyta consists of 4 'morphological' pairs, and that for one of these species the 16 chromosomes in the female germ-track consists of 4 groups of 4, corresponding to the pairs in the male. Sex chromosomes are not distinguishable; which fact does not favour application of Whiting's theory of sex-determination to Hymenoptera Symphyta. It is suggested that true relationship between the sexes is of tetraploidy to diploidy, and that initial emergence of the parthenogenesis has been by polyploid evolution.

Paris

Academy of Sciences, May 24 (C.R., 201, 1517-1596).

LUIGI CAYEUX: New data on the existence of bacteria in the old sedimentary rocks. The results of work done on ferruginous oolites, with the aid of infra-red microphotographs. The existence of bacteria in the seas is proved back to the Huronian; they probably made their appearance still earlier. It is possible that bacterial action exercised a preponderating effect in sedimentary formations.

ALEXANDRE GUILLIERMOND and ROGER GAUTHIER: The property possessed by plant cells of excreting neutral red after having accumulated it in their vacuoles.

LOUIS BLARINGHEM: The double fertilization of flowering plants and the separation of the hybrids: from the correspondence of Hugo de Vries and Léon Guignard.

SERGE BERNSTEIN: Modification of the quadrature formula of Tchebysheff.

LUCIEN DANIEL: New researches on the variations of the apogamous dandelion.

MAURICE NICLOUX: The proportion of alcohol in water from the interstitial plasmas and of protoplasmic water, in an aquatic animal, is that of the external medium in which it is immersed. Experimental demonstration for the frog.

W. SLEBODZINSKI: The realization of a variety with affine connexion by a surface plunged in an affine space.

PAUL GILLIS: The equations of A. Haar of the calculus of variations.

CHARLES JACOB: The Gibbs phenomenon in the development of series of Hermite polynomials.

ROBERT FORET: Linear operations not completely continuous.

HENRI CORBLIN: A compressor with two membranes for use with gases forming dangerous compounds with lubricants.

LEOPOLD ESCANDE and GEORGES SARATHÉ: A weir inclined with respect to the axis of a canal.

Mme. MARGUERITE MOREAU-HANOT: The theoretical study of toroidal high-tension collectors.

GEORGES BODIER: The influence of the earth circuit of lightning protectors in an electrical network.

ROBERT FORRE: The electronic lattice of the transition elements.

HENRI LACOSTE-TAYAN: The cycles of recoil of magnetic steels.

MARCEL LAPORTE: A law of emission of a radiation with continuous spectrum (white light) by xenon tubes.

MOHAMMAD MONADJEMI: The materialization of the energy of the β -rays of thorium B+C.

FRANÇOIS BOURION and EMILE ROUYER: The determination of the hydration of the ions of calcium nitrate.

JEAN COURNOT and MARC BAUDRAND: The corrosion of riveted joints. Supplementing work described in a previous communication. The conditions of working are similar, but the two plates are of different materials.

MARCEL SERVIGNÉ and ETIENNE VASSY: An application of luminescence to quantitative analysis: the micro-estimation of the element samarium. In the particular case of samarium in very dilute solid solution, the intensity of the band studied is proportional to the concentration of the active element. With concentrations between 1.07×10^{-4} and 0.082×10^{-4} grams per gram of diluent (calcium tungstate) the accuracy of the measurements is about 5 per cent.

RENÉ DUBREY and GEORGES ARDITI: The alteration of metals by carbon tetrachloride in the presence of water. Results obtained with copper and zinc are given.

Mlle. YVONNE GARREAU: The oxidation of hydroquinone by air in the presence of *n*-butylammonium sulphite.

MARCO BASSINER: The structure of cadmium nitride (hydrazoate). Description of the method employed for obtaining cadmium hydrazoate in pure crystals, with details of the crystallographic and X-ray study.

J. MALAVOY and F. JACQUET: The geological formations of Portuguese Guinea.

MILAN MARGUERITE FROILLO: Study of the submarine breccias containing dolomitic elements in the dolomitic Trias of the eastern Carpathians.

NICOLAS STOKO: The periodic variations of longitude.

EDOUARD BOURNAU: The presence of tracheids in the alternate wood of the radiæ of conifers.

MARCEL MASCHÉ and RENÉ PARIS: The constitution of scoparoside (scoparine) of *Sarothamnus scoparius*. Scoparoside is a heteroside of the formula $C_{22}H_{34}O_{11}$, hydrolysable with difficulty, giving a molecule of rhamnose and a molecule of a flavone derivative, probably a quercitol methyl ether.

RENÉ SOULIER: The embryogeny of the Plumaginæ. The development of the embryo in *Armeria plantaginæa*.

ANDRÉ TOURNADÉ and MARC CHEVILLIOT: Does the action of the vaso-dilator nerves amount to a liberation of acetyl-choline?

PHILIPPE JOYET-LAVERGNE: Distinguishing the zones of oxidation in the living cell by the method of cobalt salts. In the living cell, whether plant or animal, the chondriome and the nucleole are two constituents which possess a catalytic oxidizing power sufficiently great to transform cobaltous salts into cobalt salts, a change shown clearly by the colour change.

YVES LE GRAND: The apparent rhythm of flickering.

MAURICE FONTAINE and RENÉ GUY BUSNEL: The localisation and the nature of the flavine contained in the skin of the eel.

AUGUSTE LAFAY and BERNARD LAFAY: The introduction of artificial radioactivity into therapeutics.

Geneva

Society of Physics and Natural History, May 20.

P. ROSSER: (1) Definition of stellar colour indexes. Photometers used for the determination of colour indexes are generally standardized in such a manner that the index is zero for the A_0 stars. There may be an advantage, especially in the case of photo-electric cells, in considering the index as the difference of two magnitudes, omitting this adjustment. (2) The Wien-Planck correction in the calculation of the magnitude of a star. This calculation makes use of certain sums the handling of which is somewhat inconvenient. It is possible to replace these by certain exponentials, with an error which never exceeds 0.03 magnitude.

J. PH. BUFFLE: The origin of the calcium bicarbonate in the waters of the River Versoix (Canton of Geneva). The river contains no free carbonic acid, and is not capable of dissolving the limestone which forms its bed. As, on the other hand, the proportion of calcium bicarbonate increases from the source of the river to its mouth, the origin of the salt must be external to the river. It is brought in by waters of infiltration, which fulfil the necessary conditions for dissolving the chalk of the strata which they traverse.

G. THIÉRY and P. JAVET: The pulsation of variable stars of the Cepheid type. A study of the case where the periodic variation of the ray includes two terms, one of which has a period double that of the other.

P. BALAVOINE: The variation of the iodine value of drying oils according to their origin. The iodine values of drying oils, particularly linseed oil, vary according to the country of origin and the season during which they have been prepared. The value is higher when the oil is prepared at a higher temperature.

Vienna

Academy of Sciences, April 22.

H. MOLISCH: Influence of one plant on another which is remote from it. The principal results are given of a research arising out of the well-known property of ripe apples of accelerating the ripening of unripe ones stored with them. The full results are to be published in book form.

S. MEYER: The age of the sun, the decay constant of actino-uranium and the ratios of the amounts of lead, thorium and uranium on the earth.

N. V. SZENTPÁLY: Heating effect of radioactive minerals. A combined micro-calorimeter and thermostat is described.

F. VIERHEGGE: Loss of charge of α -particles in helium. For particles of velocity 1.08×10^8 cm./sec., the mean free paths for capture and loss are 11.3 times the corresponding values for air.

M. MLADENOVIC: Nature of manilla resin.

E. BEUTEL and A. KUTZELNIGG: Production of a brilliantly fluorescent zinc oxide by partial decomposition of basic zinc carbonate.

E. KRUPPA: Projective geometry of a Hermitian plane.

R. LINZINGER: Geometry of the Monge-Ampère differential equation of the second order.

J. KRAMER: (1) Cubic circular motion of space. (2) Geometry of the Bennett mechanism.

J. PIA: Recent researches on the Cetacea of the Vienna Miocene.

K. O. FELSCH: Stratigraphically important corals from the upper Nassefeld strata and the Troglkofel chalk of the Carnic Alps.

G. E. KIMLHAUSER: Carboniferous flora from the loess of the mill near the Rattendorf meadow in the Carnic Alps.

April 29.

FRANZIŠKA SMIDL: Observations of the diurnal variation of the electrical conductivity of the air in Fulpmes in the Stubai valley.

K. EHRENBERG: Two new remains of primates from the Miocene of Lower Austria. A right ulna and a humerus bone are described which possess characteristics of both the anthropoids and the lower primates. They are believed to belong to a new species which has been named *Austriacopithecus wienfuerteri*.

May 7.

K. HILLEBRAND: Evolution of cosmic dust clouds. A permanent change in the distribution of matter which is initially uniformly dispersed can be brought about by inelastic collisions.

E. W. KELLERMANN: Coloration and luminescence of fluorite.

K. GRAFF: Visual colour excess of bright stars near μ Cephei.

The Future of the South African Protectorates

THE statement made by General Hertzog, Prime Minister of the Union of South Africa, on his return from attending the recent Imperial Conference in London, which dealt with the question of the transfer of administrative control of the South African native Protectorates to the Union (*The Times*, July 7), has raised a grave issue in the gravest possible manner. He accuses the British Government of a dilatoriness virtually amounting to bad faith, and in the event of further delay, foreshadows an appeal to the Crown, of which the consequences both to Great Britain and South Africa would be so incalculable, that he is not prepared to accept as final the British minister's reply to pressure for early transfer.

General Hertzog clearly intended a reply to certain opinions expressed in the House of Lords in the debate on Lord Noel Buxton's motion on June 9 (see *NATURE*, June 26, p. 1083). When he went on to speak of the Government's attitude as dictated by the ballot box, he descended to a mere piece of political invective, worthy neither of its author nor of South Africa's case.

It cannot be denied that South Africa has a case; and the interests of the Protectorates afford strong, indeed almost overwhelming, argument in support of that case on geographical, economic and administrative grounds. The territories are, and must always be dependent economically upon the Union. They have no natural effective outlet except through the Union; they are dependent upon it for the employment by which their labour makes up the deficiencies of their capacity to produce. On the side of the Union any serious disparity in administrative methods might at any moment aggravate difficulties in dealing with its own native question. Nor should it be overlooked

that the Union has been generous in assistance to the Protectorates in a time of stress, although that assistance may have been granted under a misapprehension, for which General Hertzog himself is largely responsible.

Mr. Malcolm MacDonald, the Secretary of State for Dominion Affairs, showed in the House of Commons on July 9 that there had been a complete misunderstanding of the position. There had been no undertaking that transfer would be effected within any specified period. Once more he enunciated in terms the pledge, which was again repeated in the House on July 13, that no action would be taken without previous consultation of the inhabitants of the Protectorates, white and native, though he could not be brought to the point of a categorical statement that without consent there would be no action.

In delaying transfer, the British Government has displayed supreme wisdom. In the eyes of informed opinion—and in this matter the House of Lords is perhaps a better gauge of public feeling than the House of Commons, hence General Hertzog's aggrieved reference to its periodical pronouncements—the time is not yet ripe. For this the attitude of the Union Government on the native question is as much, if not even more responsible than the admitted reluctance of the Protectorate native populations to acquiesce in the change of administrative rule.

Since the passing of the South Africa Act of 1909, a great change in outlook has taken place in matters affecting the welfare and the administration of the affairs of backward peoples. At that time the anthropologist was urging the imperative necessity for scientific study of native institutions and beliefs as a basis for sympathetic administration

of native affairs. In South Africa the Government had embarked on a policy which seemed to hold out to the native an avenue of approach to a useful participation in citizenship and a share in the future development of the country through the organization of native councils. Great Britain, therefore, at that time felt justified in looking forward to a day when all the natives of South Africa might pass to South African control. Events in the political, economic and industrial history of the Commonwealth have falsified anticipation. The problem of the native population, which as a sociological question should be approached in the spirit of scientific and objective inquiry, has become an issue in party politics, while the trend of legislation, notwithstanding pledges to initiate a more liberal course of action when once the 'menace' of the native franchise was removed, has been to strengthen the colour bar and to emphasize the social and economic disability of the 'inferior' race, through the policy of segregation. It is not the least disquieting feature of the present situation that a certain section of advanced native opinion is strongly in favour of segregation and the complete separation of the two races in the interests of the native himself.

As a self-governing Dominion, it is South Africa's business to deal with her native problem as seems to her best. A white population outnumbered by the native in the proportion of four to one has need of provident statesmanship if it is to preserve its supremacy without crippling its powers of expansion. There is, however, in South Africa a growing section of opinion, in which the anthropological school of thought counts for much, that sees in the present policy of segregation as enforced by legislation, no way out for the native towards further development. In present conditions, it is true, some measure of training in various directions, educational and vocational, lies open to the native, though these conditions are perhaps less favourable than they were a generation ago. But there is little scope for the exercise of the native's powers and energy when once he is trained. For this *impasse*; the anthropologist would seek to substitute conditions such as a scientific and dispassionate survey of the situation would suggest. These, he is confident from his knowledge and experience, would, without turning the native into a black European, open the way to growth along lines congenial to native character and institutions, and yet would admit him to a

share in the development of the country, to the advantage of white and native communities alike.

These matters, however, are for the Union of South Africa to decide; but the appearance within the Union of a body of opinion critical of the dominant policy is not without its lesson for the people of Britain. Under the Imperial Parliament, the policy of native administration has virtually ceased to be a political issue. In general, parties are now united in accepting the doctrine of 'trusteeship' as the principle of government of the backward peoples of the Empire; and that in appropriate circumstances, "the interests of the native shall be paramount", has been enunciated repeatedly as the decisive formula of British native administration. In the South African Protectorates under the administration of British officials, circumstances have brought about a system of control, which if not technically 'indirect rule', approaches that method of government in some near degree. Under that system, a process of acculturation has been taking place, which is producing a system of religious belief and social organization, that if neither entirely European nor wholly African, has something of each, and yet—and this is the important factor—is both congenial to the African temperament and affords, in the eyes of competent judges, a potentiality of further cultural development along progressive lines. What those lines should be, it is the opportunity and the obligation of scientific study to assist in determining in the light of the effects of the cultural impacts which are now taking place—in short, the function of the 'applied anthropology' for which the Royal Anthropological Institute has recently appointed a standing committee (see p. 145).

Apart from the question of the obligation imposed on the Imperial Government by its pledge to consult the inhabitants of the Protectorates before any action is taken in the matter of the transfer of their administration to the Union, the crux of the problem lies in the temper with which the people of the Union of South Africa attempt to solve the problem of their own native population. Unless this is such as to afford a reasonable guarantee that it will foster rather than frustrate the steps, slow and hesitant they may be, now being taken by the natives of the Protectorates towards a cultural development, which may truly be regarded as a progress in civilization, the British Government should see no alternative but to hold its hand.

Evolution of the Holarctic Fauna and Flora

Die Holarktis:

ein Beitrag zur diluvialen und alluvialen Geschichte der zirkumpolaren Faunen- und Florengebiete. Von W. F. Reinig. Pp. vii+124. (Jena: Gustav Fischer, 1937.) 7.50 gold marks.

ONE cannot fail to agree with the author's remark in the preface to this interesting book, that the rapid recent development of zoological science has served, to some extent, to obscure the intrinsic value of biogeographical studies, which often tend to be regarded as a mere branch of ecology. Actually, biogeography, or the study of the composition, origin and evolution of the living faunas and floras, represents a higher degree of synthetic biological knowledge than either ecology or faunistics (or floristics), on both of which it largely relies for its fundamental data. The book under review must be regarded, on the whole, as a very successful attempt to treat the problem of the Holarctic fauna and flora on broad biogeographical and evolutionary lines.

The indisputable fact that the greater portion of the territory of Holarctis was either covered by Quaternary ice, or experienced the climatic effects of glaciations, was apparently the reason which made the author restrict his analysis only to the later stages of Pliocene and to Pleistocene. This course certainly simplified the task very greatly; but it can scarcely be justified in the face of many distributional facts, which obviously have their origin in much earlier geological periods. The volume of reliable palaeontological data on the distribution of life in the present Holarctic region during the Tertiary is very considerable, while geological data permit one to form some judgment with regard to the Tertiary climates, as well. The restriction of the field of study is, therefore, largely artificial, and makes the results less complete and convincing than they might have been.

The main thesis of the book, developed at considerable length and with abundant supporting evidence, is that the present distribution of Holarctic animals and plants can be explained on the basis of their evolution during, and under the influence of, repeated glaciations and of warmer interglacial periods. The maximum glaciation in the Eurasian continent forced the temperate pre-glacial forest flora and fauna to retreat to four main 'refuge areas', namely: (1) Mediterranean; (2) Armeno-Persian; (3) Central-Asian (consisting of three separate parts—Afghanistan, Tian-Shan

and northern Mongolia); and (4) Eastern-Asian (including south-eastern China and Japan).

In North America, the flora and fauna of the same pre-glacial type retreated also into four refuge areas: (1) Atlantic, comprising Florida and adjoining lowlands; (2) Mexican (subtropical); (3) Pacific, extending along the southern Rockies; and (4) Alaskan. The subsequent retreat of glaciers resulted in re-invasion of more northern regions from the refuge areas, where in the meantime distinct races and even species were produced by isolation. This re-invasion was not simultaneous everywhere, since the maximum glaciation, according to the author, both commenced and ended in Europe and in North America earlier than in Asia. This accounts for the considerable European element in the present Siberian fauna, and for the great affinities of the latter with the American one. Certain elements were slower in the re-invasion, and some of them remained restricted to refuge areas and represent well-known examples of discontinuous distribution. Repetition of retreats and advances of animals and plants during successive glaciations served to complicate the resulting distribution still more, and some of the details cannot be elucidated as yet.

Of course, this is only a very brief and greatly simplified summary of the author's ideas, which are developed with a wealth of data. These ideas certainly appear sound and well documented, if not wholly new. It is, however, obviously inconsistent to disregard the influences to which the Holarctic fauna and flora must have been subjected from the more southern zones of the continents under study. The author attributes to glacial climates the power to drive animals and plants into what are now subtropical zones; but he appears to ignore a northward pressure of subtropical elements (or those derived from them) during the warmer inter-glacial periods. If the displacements of climatic zones are admitted, it is only logical to study all their implications, including the influence of southern faunas and floras on those of Holarctis. The author prefers to be one-sided in this respect, and goes so far as to state that the present Mediterranean and even the Eremian zone cannot be separated from the Holarctic because they partly served as refuge areas for Holarctic plants and animals during glaciations. Such a sweeping disregard of deep ecological, floristic and faunistic differences which exist between deserts and temperate forests will not be accepted by other biogeographers.

A similar disregard of ecology is apparent in many parts of the book, representing probably a reaction against undue preponderance of the ecological point of view in modern biogeography. As an example, it is sufficient to point out that the author uses the words 'steppe' and 'desert' almost as synonyms, and often speaks of "Steppen und Wüsten" as of a single biogeographical unit, while there is nothing but a superficial similarity between these two types of habitat, which are profoundly different in their distribution, climate, ecology and in their plant and animal population.

It would be easy to criticize various lesser

points in the author's theories, but this would be scarcely fair, since the book is clearly a first and incomplete attempt to present a connected evolutionary history of the Holarctic fauna and flora. The author has certainly succeeded in conveying the idea of slow climatic changes causing movements of plants and animals, and resulting in complicated distributional patterns of the present day. For this alone the book must be regarded as an outstanding contribution to biogeography in the modern sense of the word, and is certain to lead to fruitful discussions and to stimulate new researches. B. P. UVAROV.

Early Science in Cambridge

Early Science in Cambridge

By Dr. R. T. Gunther. Pp. xii+513+68 plates. (Oxford: The Author, The Old Ashmolean, 1937.) 42s. net.

A GOOD many years have passed since Dr. R. T. Gunther began to discover at Oxford the great store of old astronomical, mathematical, and other scientific instruments which enabled him to illustrate the development of scientific studies in that University from their earliest beginnings; discoveries that have resulted in the preservation of much valuable material, which might easily have been lost, in the admirable Museum of the History of Science which he has arranged in the Old Ashmolean building.

Having thoroughly explored the resources of Oxford, it was natural that Dr. Gunther should turn his attention to Cambridge. There he found that while the existence of interesting objects was known to a few, no one had made a systematic examination of the ground. When, therefore, he expressed a desire to undertake this work, his suggestion was welcomed, and all necessary facilities were afforded him by those in a position to give him help. It was further arranged that an exhibition of the results of his labours should be set out in the Old Schools and be on view at the end of the Easter term, 1936. Dr. Gunther threw himself into this task with characteristic energy, and the results far exceeded all expectations.

From dusty cupboards in laboratories, from the corners of college libraries, and from seldom-opened museum drawers, he brought together a wealth of old apparatus which surprised even those who had some knowledge of the hidden

treasures of Cambridge, and aroused great interest in numerous visitors during the all too short time the exhibition was open.

The historical and biographical notes which Dr. Gunther accumulated in the course of his researches, and the catalogue of the exhibition which he compiled form the basis of this book, which to do it justice must be regarded more as a source book than as an orderly treatise.

In his introductory chapter, Dr. Gunther wisely deprecates unprofitable controversy as to the relative age of our two ancient universities, and leaves their origins wrapped in the mists of antiquity, but by interesting quotations from William Harrison (1577), and other early writers, he shows the convenience and importance of the site of Cambridge at the head of a navigable water-way by which commodities could be brought to the town when roads were but miry tracks. The paragraphs headed "Roads and Communications", "Travel by Air", and "Railways", contain information which will be new to most Cambridge residents to-day, and the clauses relating to Cambridge in the Assessing Act for the Eastern Counties Railway, printed *in extenso*, give an amusing account of the obstacles placed by the University in the 'forties in the way of any of its younger members who wished to travel by train. A brief account of Fen drainage schemes and notable floods has especial interest in view of recent experiences.

The second chapter, entitled "Mensuration", is essentially an excerpt from the exhibition catalogue, prefaced by some historical matter relating to Sturbridge Fair and to the University in its capacity as an inspector of weights and measures.

Dr. Gunther deals next with mathematicians and mathematical instruments, and following the method he employs throughout the rest of his book, gives in chronological order brief biographical sketches of the eminent men who have cultivated this study in Cambridge, incidentally rescuing from oblivion many lesser lights. Thus, while Newton holds the field, Briggs, Oughtred, Seth Ward, Barrow and others are not forgotten, and the chapter is illustrated with excellent plates of the splendid set of mathematical instruments made for Roger North and now in the possession of Jesus College, and of the perfect specimen of Oughtred's circular slide rule which came to light in the Cavendish Laboratory.

Mechanics and physics are dealt with in the same way, the great wealth of material being handled under such sub-headings as weighing the earth, sound, heat, light and colour, magnetism and electricity.

A long and richly illustrated chapter is devoted to astronomy, and as is but natural, much space is allotted to astrolabes and sun-dials. It may, however, be doubted whether the importance of Dr. Dee justifies the amount of attention given to him.

Two short chapters dealing with geography and meteorology bring us to chemistry. Here the somewhat elusive figure of Vigani, the first professor of chemistry, comes to life with his cabinet of *materia medica* still preserved at Queens' College, and the better known names of Smithson Tennant and Wollaston receive adequate attention.

Chemistry leads on to medicine, and while "pestilence walks at noon day", a strange assortment of practitioners and quacks passes across the stage. This chapter is packed with curious lore, and leaves the reader with a wholesome respect for the stamina of those of our ancestors who managed to survive the attentions of their medical attendants.

Anatomy, physiology and pathology are dealt with next, and on almost every page will be found the record of some curious fact or the revelation of some quaint personality. Particularly interesting are the accounts of the researches of Glisson and Stephen Hales.

In the account of zoology, John Ray and his friend Willughby hold pride of place. Two of Ray's letters are reproduced in facsimile, and a number of others now published for the first time are to be found in an appendix. Ray, too, is prominent in the section devoted to botany, and Stephen Hales tells the story of some of his most important botanical discoveries in his own words.

The study of geology in Cambridge, being based on the foundation of Dr. Woodward, it is interesting

to have before us his will *in extenso*. It can only be regretted that the annual inspection of his collections, to be followed by a dinner, to which he attached so much importance, has been allowed to fall into abeyance.

The appendixes with which this work concludes are not the least valuable part of it, and Sir Thomas Selater's practice of fruit and fish culture towards the end of the eighteenth century will have interest for many.

Up till the middle of last century, it was still possible for one man to attain distinction in more than one branch of science. The arrangement of the matter of this book under subjects leads, therefore, to the appearance of the same individual in different categories and tends inevitably to a certain amount of repetition. This, with the intercalation of excerpts from the exhibition catalogue, produces a somewhat patchwork effect. The first inconvenience could scarcely be avoided, but if the catalogue had been printed as an appendix, the narrative would have become more continuous and satisfying.

In a work of this kind, some slips and misprints are bound to escape the vigilance of the author. Many have been noted, but not in undue number or likely for the most part to mislead a reader seriously. A few may be mentioned. Darwin worked at Downe, not Dover. Prof. G. H. F. Nuttall's name is unfortunately omitted from the list of the Quick professors, and the press set up in 1752, at which astronomical works were printed, had its home in Pembroke, and not, as might be inferred from p. 79, at Queens'.

Though the book suffers from a certain lack of orderly arrangement and from rather meagre documentation, a vast amount of interesting and entertaining information culled from a great variety of sources, many of them obscure, has been brought together within its covers. All Cambridge men should be grateful to Dr. Gunther for making it possible for them to become acquainted so pleasantly with the personalities, aims and achievements of their scientific forbears, and for compiling a work which should be in every college and departmental library. Senior members of the University who keep it handy on their shelves will find it a sort of scientific "Gunning", admirable for browsing in at odd moments; for most junior members it will probably prove too expensive.

In conclusion, we would re-echo the hope expressed in the author's preface, that among the institutions of the University a modest room or two may be found, where the more interesting and important of the exhibits got together last year, suitably displayed and labelled, may find a permanent home.

A. H.

The Structure of the Flower

Floral Morphology:

a New Outlook, with Special Reference to the Interpretation of the Gynæceum. By E. R. Saunders. Vol. 1. Pp. viii+132. (Cambridge: W. Heffer and Sons, Ltd., 1937.) 3s. 6d. net.

THE history of plant morphology shows a number of more or less distinct phases. The earliest phase was one of description, including the recognition of morphological categories and the introduction of terms. Later the idealistic concepts of Goethe laid the foundation of much that is still orthodox. With the advent of Darwinism, there commenced a long period of explanation in terms of use and, on the whole somewhat later, attempts to trace the evolution of organs. At the present time, all these earlier phases seem to be revived in a new interest in plant structure, with the introduction of certain new methods and theories.

The vast majority of existing seed plants are characterized by possessing flowers clearly marked off from the vegetative parts of the plant body. The evolutionary history of the flower is still obscure and, even as a preliminary to research on this problem, there is an urgent need for clarification in our knowledge of the morphology of its component parts. Botanists are not all agreed as to whether it be a simple stem bearing modified leaves, a modified branch system, or essentially a structure *sui generis*. All parts have been subject to detailed and comparative examination: perianth, andræcium, and gynæceum (gynæceum). The composition of the latter has, however, been the subject of most recent research. The numerous papers of Miss E. R. Saunders have made botanists familiar with the theory of carpel polymorphism. None will deny the importance of her work in directing attention to the many peculiarities of arrangement, anatomy, and behaviour to be found in the ovaries and their associated parts in both monocotyledons and dicotyledons. In a first volume on floral morphology, Miss Saunders summarizes her views on the architecture of the flower, with special reference to the gynæceum, in an introduction, and outlines on this basis the flower structure of thirty-nine families. A student unacquainted with the new concepts would probably find the book somewhat difficult reading, partly because of the very few illustrative drawings. The size, founts, general format, and low price of the book are all excellent, and it is to be hoped it

will be widely read and used, especially as a guide to laboratory work by teachers and students. If it gives stimulus to the detailed dissecting of flowers and a study of their anatomy in academic institutions, it will have fulfilled a most important and urgent need.

The special theory of carpel polymorphism, which is the central theme of the book, is "in accordance with the view that in true apocarpous the individual ovary is formed of a single carpel, which arises as a separate structure, but that in syncarpous and pseudo-apocarpous forms it is composed of two kinds of carpels, sterile and fertile". Two main types of carpels are distinguished: valve and consolidated. The former shows pinnate venation, marginal ovules (when fertile), and when present alone generally forms an apocarpous gynæceum. The consolidated carpel has a pair of strongly developed bundles close to the mid-line (with or without a median bundle). The ovules are usually borne on either side of the mid-line, and the consolidated carpel is, in syncarpous ovaries, generally fertile. It may be contracted (solid carpel) or expanded (pseudo-valve carpel).

Though based very largely on the number and relationship of the vascular strands in the flower, it is claimed that the principles outlined "dispose of many morphological fictions, including hypothetical splittings and unions, hypothetical suppressed whorls, 'commisural' stigmas, 'false' partitions, 'free central' placentation and epigyny, as traditionally interpreted, while 'parietal' and 'axile' placentation and 'septicidal' dehiscence now have an altered significance. They provide an explanation of obdiplostemony, various forms of fruit dehiscence, and many other hitherto unexplained features".

There is no doubt that, considering the evidence as a whole, Miss Saunders has presented a strong case. It is probable that not all her interpretations will be accepted by future investigators; but they will have to be examined from the point of view of the evidence she has provided, even if other viewpoints be also considered valid. The evidence is particularly strong in the *Rhodadales* (including the *Cruciferae*) and in the *Liliaceae*. Some of the families in which it is probably more difficult to provide an acceptable interpretation of the structure of the gynæceum on the basis of carpel polymorphism, such as the *Leguminosae*, are not included in this volume.

W. B. T.

Nauka Polska:

jej Potrzeby, Organizacja i Rozwój. (Science and Letters in Poland: their Needs, Organisation and Progress.) Tom (Vol.) 22. Pp. ix+433. (Warszawa: Kasy Imienia Mianowskiego, 1937.)

VOL. 22 of "Nauka Polska", an annual publication edited by Prof. S. Michalski and issued by the Mianowski Institute for promoting Science and Letters in Poland, is devoted largely to a series of papers on the influence of science upon human culture and progress. Among several noteworthy contributions is one by Prof. S. Ossowski, who deals with the influence of the personal opinions of the man of science on researches in the domain of the social sciences. He goes on to examine the effect that personal political and social convictions can have upon the course of a research worker's investigations in such subjects as sociology, political economy and anthropology, that is, in sciences directly contributing to progress in social life.

The influence of physics upon the development of modern civilization is the theme of a contribution from Prof. S. Szopeniowski, who endeavours to show how the theories of pure physics and the exact sciences have moulded opinion with regard to modern conceptions of the universe. Another interesting memoir in this issue of "Nauka Polska" is that by Mme. Danilewicz, who wishes to direct attention to the scientific work conducted between 1805 and 1831 at the former lycée of Krzemieniec in south-east Poland (Volhynia). The concerted attempt of an enthusiastic group of specialists in physics, chemistry, mineralogy and botany to create a local interest in the flora and natural resources of this district made a most promising beginning, but was afterwards suppressed for political reasons.

In the notes referring to scientific events in Poland and abroad there is a brief account of the British Association meeting at Blackpool, and reference is also made to the activities of the Research Co-ordination Committee.

P E P (Political and Economic Planning)

Report on International Trade: a Survey of Problems affecting the Expansion of International Trade, with Proposals for the Development of British Commercial Policy and Export Mechanism. Pp. vii+302. (London: Political and Economic Planning, 1937.) Paper boards, 8s. 6d. net; cloth, 12s. 6d. net.

THE group of industrialists, distributors, local government officers, university teachers and others who have produced this comprehensive monograph claim allegiance to no political party and are concerned solely with the problems of social and economic reconstruction. It is a lengthy report and contains a mass of statistical and other matter, bearing on the mechanism, finance and politics of international trade. The writers conclude that the idea of sweeping away international trade barriers is impracticable and is being replaced by organized exchange between nations, which, however, should be more constructively planned. The report discusses at length such constructive measures by taking into account not merely economic needs but also politics, psycho-

logy, transfer difficulties and other relevant factors. Within the policy of the State there should be scope for the initiative of individual traders, especially in co-operative steps. International trade will probably become permanently a smaller proportion of total trade, and will certainly not return to past conditions; but on new and constructive lines there should be a measure of revival. Finally, it may be noted that the report examines frankly the role played in present trade by the economics of war.

Physiology in Health and Disease

By Prof. Carl J. Wiggers. Second edition, thoroughly revised. Pp. 1124. (London: Henry Kimpton, 1937.) 42s. net.

THE second edition of Prof. Wiggers' book follows the first after an interval of only two years. Special emphasis has been laid on subjects of clinical importance and the book is really a general textbook of clinical science. Chapters are devoted to such subjects as oedema, sleep, acidosis, peripheral vascular disorders, blood-pressure, valvular lesions, fever and diet. The section dealing with the circulation is particularly detailed.

The book covers much the same ground as Samson Wright's "Applied Physiology"; but it is about 35 per cent larger. No one man could speak with the authority of detailed knowledge over so wide a field, and the judgments of this book sometimes appear superficial. Its main value lies in the fact that it contains a very large number of references to original work and to detailed reviews. It should be useful to students and to those who seek access to literature dealing with subjects outside their own speciality. Prof. Wiggers is a physiologist, and his book will probably be more admired by physiologists than by clinicians.

The Physics of Electron Tubes

By Dr. L. R. Koller. (International Series in Physics.) Second edition. Pp. xvii+234. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 18s.

THE first (1933) edition of this book has already been favourably reviewed in NATURE (133, 968; 1934). The present second edition has been slightly enlarged, especially by the addition of short treatments of such topics as electron optics, secondary emission multipliers, "ignitrons" and positive ion emission.

The title of the book would be more appropriately "Introduction to the Physics of Electronic Devices", as it deals within its relatively short space not only with 'electron' tubes, that is, hard valves and photocells, but also includes gas-filled relays and even two chapters on photo-conductivity and photo-voltaic cells. The treatment is clear, bringing out the essential points. Intricate mathematics has been avoided by stating in such cases finished results; however, Richardson and Schottky's equation, and the $3/2$ power law have been derived in a special appendix.

Very useful for the beginner is a collection of problems (with solutions) and with the aid of a good list of references added to each chapter, he will be able to find his way to more detailed study of the subject.

A. B.

Ammonolatry: The Life Element*

By Prof. Henry E. Armstrong, F.R.S.

(To a muted, musical undercurrent reminiscent of *Aida*, in face of a moving, desert panorama with camels.)

FOR several months, while I have been confined to my room, I have had before me two unusual and remarkable books which are of special interest to me, at a time when we have to admit that far more consideration must be given to the manner in which chemists are trained. The books are E. C. Franklin's "Nitrogen System of Compounds" and N. V. Sidgwick's "Organic Chemistry of Nitrogen", in both of which I have particular reason to be interested.

About thirty years ago, soon after the great San Francisco earthquake (1906), I visited Leland Stanford University at Palo Alto. The founder was doing penance: he had been tossed from his pedestal and was standing upside down, with his head through the stone pavement: I believe he was ultimately restored to righteousness without a feature injured. Chemistry was well on its feet. The professor, Edward Curtis Franklin, was at an early stage in the inquiry, now so associated with his name and school, into the properties of liquid ammonia in comparison with those of water, especially as an electrolytic solvent: though boiling at -33.35° , it comes close to water in activity. Liquid ammonia was being brought into use at that time as a refrigerating agent, and Franklin had command of the technical product.

It may be mentioned here in parenthesis that Gore in his earlier work on the subject (1872-73) was forced to prepare the liquid separately for each experiment, by heating ammoniated calcium chloride in the tube containing the substance to be tested. He tested the solubility of more than five hundred substances. He had great difficulty in securing support for his work—in those prehistoric days it was considered to be of little interest. He made a similar study of liquid hydrogen fluoride, and all but isolated fluorine. Few are left to remember his persistent pioneering efforts in advocacy of pure research, for which he made a great personal sacrifice: unfortunately, he was not original. I had the privilege of being made his confidant and always regretted that he

had so little encouragement. We were then near to the renaissance period, but so low was the ebb of curiosity that Frankland, Vernon Harcourt and others were suggesting that a list of subjects for research should be prepared. Actually the main cause of activity was not Kekulé's benzene formula but the discovery by Kolbe and others, after the 1870 war, that research work could be made of commercial value. The poor professor disappeared but academic training began to lose its value; now, after a second war, in Germany, freedom of thought is gone. She may have gained much commercially but she has sold her scientific soul. Our task is to make the same change impossible here: it is already set in, largely through the influence of commercialism.

Franklin's reason for entering on the inquiry is stated by him as follows:

"In the autumn of 1896, Hamilton P. Cady, then an undergraduate, was working at the regulation course in quantitative analysis. Observing after a time that the young man was becoming bored with the task, the writer, at the time giving instruction in analytical chemistry, proposed to him that he prepare several of the cobaltamine salts and confirm the composition of one or two of them by analysis. Some days later, with a beautifully crystallised specimen of one of these interesting salts in his hand, Cady stated that the ammonia in these and other salts containing ammonia must function in a manner very similar to that of water in salts with water of crystallisation. He suggested furthermore that liquid ammonia would probably be found to resemble water in its physical and chemical properties. As a direct consequence of Cady's suggestion has followed all the work done in this country on liquid ammonia."

Franklin died on February 13, 1937. We have to lament the loss of a colleague who could still regard chemistry as a practical subject but take notice of theory in general. His work on ammonia, already of no slight value, may some day rank high when the great problem of electrolytic conductivity is discussed with knowledge and without prejudice: as yet, it never has been. Franklin makes close comparison, compound by compound, of corresponding members of the oxygen and nitrogen systems. The ammonia work, however, is far from sufficiently described in his book. I had hoped the original papers would have been largely reproduced in readable form. If his friends were to provide a reprint it would be a pious act and a great boon to students. None the less, it is a most valuable conspectus.

Sidgwick's "Organic Chemistry of Nitrogen" is a book of very different type. Franklin would

* The proof of this article was corrected by Prof. Armstrong only a week before his death on July 18. The article represents, therefore, the final expression of the frank and critical views which he held upon the training of chemists and subjects of research. Whatever significance may be attached to these views, the fact that, while on his dying bed, he desired to make the two volumes mentioned in the article the subject of a contribution to NATURE, is a remarkable tribute to the active attention he gave to scientific subjects right unto the last. Prof. Sidgwick's book, to which Prof. Armstrong refers, was reviewed in NATURE of July 3.—The Editor.

take us back to the worship of Jupiter Ammon, begun in the dry distillation of camel's dung. Sidgwick would have us 'resonate' to the latest doctrine of electro-valency. The first edition of his book was published in 1910; it was a positive thriller. Sidgwick gave me a copy, which I have always prized; this has rested on a shelf near to my elbow and has often been taken down; my hope that the new edition would have similar attraction is disappointed. Two Oxford fellows, T. W. J. Taylor and Wilson Baker, seem to have been mainly responsible for the new edition, but the names of a host of other helpers are given. Sidgwick only contributes seven pages of introduction and a page or two on *Chelate Ortho-nitro-phenol derivatives*, which show that he is now devoted to the fashionable morganatic game of crab catching, an appropriate exercise for the Upper reaches of the Thames.

The plan remains what it was. The intention is said to have been to give an account of the simpler organic compounds and to discuss some of the interesting problems which these properties present, giving so far as possible adequate explanation of the necessary physical background. The authors have not the practical experience and critical judgment necessary to carry out their task in a way to make the book of practical value to students who would train to be chemists—of whom there are very few at Oxford. It is not a beginners' book and makes high demands upon previous knowledge, without explanation plunging the reader forthwith into technicalities known only to the specialist and impossible for the ordinary reader to understand. Though highly discursive and scrappy at times, necessarily a book written at such length contains much that is interesting, but no training in judicial method is to be gained from its use.

At least half of what is regarded as the most intellectual of our youth is attracted to the University of Oxford; this element is all but absolutely classical in its outlook. Oxford needs medicine of a very different order from that represented in Sidgwick's book: medicine that will make it a school of practice in chemistry, not one of elocution. The University is receiving large funds but its traditions are such that it does not attempt to train men to be efficient and effective laboratory workers. It has grown up upon words and lives upon them. The Oxford way is to enforce knowledge of what is done as a preliminary to doing work—but you cannot learn a subject like chemistry without *doing* from the beginning and all the time. The book will suit Oxford youth able to memorize the purple patches and offer them up on the examination altar, hoping on leaving the Examination Schools to find an

emissary of I.C.I. awaiting their return with the prized admission card to an assured haven of research. They, however, will have had little or no effective training in chemistry but only parrot instruction in structural formulae.

In the first line of the brief introduction to the book the author at once plunges into the valency problem with full measure of 'noughts and crosses', mainly dealing with *Resonance*, blankly asserting that:

"The conception is the most important development which structural chemistry has had since it was extended to three dimensions by van 't Hoff in 1874. It is a result of the application of wave mechanics and could not have been deduced from classical dynamics; but its essential conclusions can be stated very simply. If a molecule can have two or more different structures in the ordinary organic sense of the term, then under certain conditions its actual state is neither one nor the other but something intermediate between the two, which partakes to some extent of the properties of both but cannot be expressed in the usual structural symbols. The molecule is then said to exhibit resonance and to be a resonance-hybrid of the two or more structures.

This is a declaration which I hesitate to endorse. In his recently delivered presidential address to the Chemical Society (*J. Chem. Soc.*, April), our would-be trumpeter of nitrogen speaks with even greater modesty and exceptional clearness. We are there told that it was a product of the obscure doctrine of wave mechanism.

"The general conclusions of the theory of resonance are of great practical importance, especially to the organic chemist. But it is not to be expected that more than a very few organic chemists will have either the time or the ability to master these mathematical operations. It is therefore obviously our duty to express—or to induce the wave-mechanicians to express—the results in the simplest terms that are possible and this can really be done quite easily. The use of the technical language of wave mechanics for this purpose is quite unnecessary and in fact misleading, for it makes the non-mathematical reader think that as he can't understand the language he can't understand the conclusions either, which is quite untrue; and not uncommonly, I think, it leads the non-mathematical writer to believe that if he knows the technical terms he must understand their meaning, which is by no means always the case."

I have known strange things said in chemistry but have never before been quite so stood upon my head.

Passing to the examples given, with carbon dioxide we have the three formulae:

"According to the theory of resonance, since all these formulae represent linear molecules and should have about the same stability or heat of formation, resonance must occur and the actual state of the molecule will be something intermediate between

them which we call a resonance hybrid, which will have a greater stability and heat of formation and a rather smaller distance between the atoms, than correspond to any one of the formulae. Experiment shows that this is so. Further, since the last two formulae are really the same, they must be represented to the same extent in the actual state of the hybrid, which therefore should be non-polar, as it is found to be."

According to this, resonance would seem to be a state of suspended animation in a molecular system with a shortened waist. Is not this "Much Ado about Nothing"? In what way it is an advance upon van 't Hoff is not clear. Kolbe was angered that van 't Hoff should introduce metaphysics into chemistry—what he would have said to Sidgwick passes expression. I am open to the retort, I know, that van 't Hoff was justified, but he had a solid model to build upon.

One of the more important applications of the conception of resonance is to the explanation of the power of hydrogen to serve as a bivalent link. There is no doubt, says Sidgwick, that a hydrogen atom is able to hold two oxygen atoms together. To me the evidence is entirely inadequate, nor is his present argument impressive.

"The crystallographers," he says, "have actually measured the length of this O-H-O link (about 2.5 Å) which they call the hydrogen link but the idea which formerly prevailed that this link, like co-ordinate links in general, was due to the hydrogen taking up two more shared electrons (so that it had four in all) is now known to be impossible, since a hydrogen atom cannot hold four electrons with sufficient firmness. The only alternative explanation is that we have resonance between the ordinary form and one in which there is an oxonium cation and an R-O anion:"

Truly a soul-saving set of symbols. Faint praise ; scarcely hanging evidence. The nonchalance with which the inability to carry more electrons is treated and a new hypothesis at once found is amusing. Still better follows :

"The most extensive group of organic substances whose behaviour is determined by resonance is that of the aromatic compounds. It was recognised from the beginning that the two difficulties in the way of Kekulé's formula for benzene are, first, that we should expect two ortho di-derivatives ; secondly, that benzene should have the reactivity of an ethylene derivative, whereas in fact it behaves almost always as a saturated compound. The conception of resonance removes both of these objections at once : the first because we assume the state of the ortho-compound to be permanently half-way between the two formulae and the second on account of the in-

creased stability which the resonance must produce. The last point can be determined experimentally from the heats of formation."

Such a statement cannot be taken seriously and it suggests insufficient historical and practical knowledge of the subject. I was one of the earliest workers with benzene, beginning in 1868. We never treated Kekulé's formulae seriously—except for the purpose of registering the assumed disposal of substituent affinities : apart from the few who 'hammered' the idea for their own purposes, we thought of the two forms as present, if at all, in balanced proportions. The benzene symbol was used, not as a structural expression but as a convention in expressing interactions. We soon learnt that benzene had not the reactivity of an ethylene derivative. This led me to introduce the Centric formula.

The X-ray workers in course of time may help us out of our difficulty, but they are very slow. What are the forms of carbon : what of the form of that in benzene ? The paraffins are the only hydrocarbons containing diamond carbon. We know scarcely anything of paraffinoids generally. Edgar's work with heptanes shows that isomerides differ greatly, presumably owing to shape and difficulty of packing. Rumour goes that a paraffin has been made which won't pack and therefore declines to solidify—too resonant, I suppose.

Benzene, we know, contains a second form of carbon, which I would call *ethenoid*. The centres of the atoms are in a plane, not zigzagged, the distance between them less than in diamond carbon. What is hexamethylene—benzene with six "electronic" pits filled in ? It is little but a copy of benzene in appearance and properties.

During my lifetime the theory of valency has been developed from remarkably simple beginnings. When I began with Frankland in 1865, I heard his first course of lectures at the Royal College of Chemistry, published in his well-known book. He adopted Crum Brown's Graphite formulae, behind which lay the tetrahedral conception. Carbon was a wooden ball with four holes in it. He had assimilated Kekulé's formulae. I hold a paged proof of the later edition of his book in which he has written in all these. The original struggle between Kekulé and Frankland was over a fixed maximum of valency, that need not all be exercised but partly in abeyance. Kekulé as a joke copied Munchausen's method of shooting ducks on a ramrod.

Graphite is the puzzle—it seems to combine the two forms of carbon. This comes out very clearly in the model (Fig. 1).

The crystal is shown to consist of flat phenoid rings in parallel planes, 3-4 Å. apart, more than double the distance between two atoms in the

plane ring. When oxidized, oxygen atoms seem to penetrate directly into the wide space between layers and this plane is porous to other agents also. I seem to see the atoms as a bird-like structure, with unequal wings, one paraffinoid about double the length of the other one: the other, the shorter, ethenoid as in benzene.

Fig. 1.

MODEL OF GRAPHITE. FROM *Chemistry and Industry*,
AUG. 14, 1936.

Two forms of valency ultimately emerged—which acquired precision only when one was seen to be fixed by the *Electronic Charge*; the other being that which Pickering and I termed *Residual Affinity*. I discussed this very fully in March 1886 in the *Proceedings of the Royal Society* in a paper on electrolytic conduction in relation to molecular composition, valency and the nature of chemical change. In the previous year (March 1885) I dealt fully with the conditions of chemical change, a subject entirely left out of account in modern times. Then in 1888 I discussed the origin of colour and formulated the explanation since known as the Quinonoid Hypothesis (*Chem. Soc. Proc.*, March 1888).

I postulated a triple unsymmetrical absorbing system, such as that in quinone.

I soon discarded mere material absorption and taking iodoform as type, assumed that the residual affinities of the iodine atoms came into play as absorbent centres.

In fact, I became dotty at an early stage in my career. I was specially fascinated at the time by fluorescent compounds and triphenyl methane derivatives. My colour hypothesis is applicable to all ethenoid properties, and what I set out to explain fifty years ago is little short of what Sidgwick would now explain. I doubt if there be much difference between us, but having read

the classics early, I have always been held up by the caution:

What's the use of Mercators
Tropics, Zones and Equators.
They are merely conventional signs.

Kekulé wrote an imperishable sign upon the fair face of our science when he introduced the simple hexagon. This expresses the one fact that is established—that six carbon atoms form a symmetrical complex, providing a convention which permits us to register and discuss isomerism in particular.

The colour of meta-compounds, I early asserted, was merely a case of the absorbent centres being in part formed between contiguous molecules—that is to say, extramolecular; whilst in para- and ortho-quinones it is within the molecule, intramolecular.

Whatever resonance hybrids may be, do or suffer, they have little practical significance. To take up time in indoctrinating students at the university with such vagaries is not justifiable. At the moment we are in sorest need of chemists—it were time that the University Grants Committee or similar body intervened to secure rational, practical training for those few who will give serious attention to the several subjects to be studied.

Students have to be taught according to their dispositions. The biological type is very rare; no greater perversion of the type exists than the ordinary biochemist, who is so-called because he works with material of living origin. The flag can be carried by very few. Mathematics beyond more than a very elementary stage is also without appeal to the chemist proper: the mathematician is a machine—prepared to let it be granted and act accordingly. The chemist should be inspired with feeling and only ask for truth and substance; he should go straight to Nature. Of course, the majority who inflict themselves upon the natural sciences are just machines. The only teacher is experience.

The fact is, we forget how much that is taught as chemistry is mere convention. The hands-across, down-the-middle, business of "The Lancets". The "bridged-ring" is just Huck Finn, let-on stuff, yet the majority swallow it whole. Kekulé so demoralized chemists by his Ring that they have no hesitation even in giving it a handle, a bridge. Benzene must be a solid block of atoms—in so far as atoms made of electrons can be solid.

For a book on the chemistry of nitrogen, the most wonderful of all the elements in forming character—the determining element of life—to be of outstanding value, it must make manifest the sympathy which only long experience in the laboratory begets and inculcate habits of scientific

thought that will be of service to the student who desires to be a working chemist or to teach the subject in our schools. It is possible to reach the standard of knowledge required for a 'first' without acquiring these habits; this would not matter were it not that Firsts go into schools and stagnate. The failure of Firsts in the schools is the out-

standing calamity of the costly attempt to introduce scientific training into education made during the past seventy years.

Chemistry at present is a sick man—"mostly conventional signs". Something less Snarkian is needed than "to measure the value of an idea in terms of incomprehensibility."

Darwin in Uruguay

By Dr. J. D. Falconer

H M.S. *BEAGLE*, under the command of Capt. Fitzroy, sailed from Rio de Janeiro on July 5, 1832, for the Plata and anchored at Montevideo on July 26. For more than a year the ship was employed in surveying the extreme southern and eastern coasts of South America. The Plata was used as a base and to it from time to time the *Beagle* returned. Thus Charles Darwin, the naturalist aboard, had several opportunities of making closer acquaintance with the northern shores of the estuary and more particularly with the natural history and geology of the Banda Oriental, by which name the Republic of Uruguay, to the east of the Río Uruguay, was at that time known.

During the nineteenth century, Maldonado Bay at the mouth of the estuary was a favourite anchorage for ocean vessels. A strip of sand lined the margin of the bay and provided a playground for the men of the sea. In 1832 Darwin spent ten weeks at Maldonado and procured "a nearly perfect collection of the animals, birds, and reptiles" of the vicinity. He described Maldonado as "a most quiet, forlorn, little town: . . . separated from the river by a band of sand hillocks about a mile broad: it is surrounded on all other sides by an open slightly undulating country, covered by one uniform layer of fine green turf, on which countless herds of cattle, sheep, and horses graze. . . . The scenery is very uninteresting; there is scarcely a house, an enclosed piece of ground, or even a tree, to give it an air of cheerfulness"¹. To this day Maldonado retains its secluded aspect, being overshadowed by the modern resort of Punta del Este on the eastern horn of the bay. The sands, however, are now grassed and treed over, the pastures fenced and decorated with plantations, rail and road communications developed and frequented, and the landscape dotted with houses and gardens and cultivated fields.

It was at Maldonado that Darwin's attention was directed to the occurrence of vitrified siliceous

tubes (fulgurites) in the sand dunes, similar to, but shorter than, those described from Drigg in Cumberland in 1814². These tubes, believed to be formed by lightning, are still found at Maldonado but less frequently than before, on account of the cover of vegetation.

Between Maldonado and Montevideo along the northern bank of the Plata, Darwin again remarked upon the absence of trees and the uninteresting character of the grassy plains, decorated only by occasional hummocks of granitic rock. He concluded somewhat hastily that in spite of abundant rain and a favourable climate "herbaceous plants, instead of trees, were created to occupy that wide area"³. However this may be, within the last hundred years there has been much successful afforestation, and along the shores of the estuary and in many parts of the interior the aspect of the country has been completely changed.

In November 1833, Darwin made an excursion into the south-western corner of Uruguay, from Montevideo to Colonia Sacramento, and thence to Mercedes on the Río Negro. By this time, after some experience of the pampas of Argentina, his opinions of the scenery and amenities of the Banda Oriental had undergone a change. He wrote: "I find that I look at this province with very different eyes, from what I did upon my first arrival. I recollect I then thought it singularly level; but now, after galloping over the Pampas, my only surprise is, what could have induced me ever to have called it level. The country is a series of undulations, in themselves perhaps not absolutely great, but as compared to the plains of St. Fe, real mountains. From these inequalities there is an abundance of rivulets, and the turf is green and luxuriant"⁴.

On this expedition, Darwin visited the Arroyo de las Vivoras and Punta Gorda on the left bank of the Río Uruguay. From Mercedes he rode to the Sierra del Pedro Flaco, 20 miles up the Río Negro, and examined the natural sections in the

cliffs of Perika. He returned in a direct line across country to Montevideo, having been absent from the port for fourteen days. The *Beagle* sailed from the Plata for the last time on December 6, 1833.

Prof. Karl Walther, of Montevideo, has been at some pains to identify the exact spot on the bank of the Río Negro that Darwin visited, and he has come to the conclusion that the "cliffs of Perika" are those of the Cerro de los Claveles at the confluence of the Arroyo Perico Flaco and the Río Negro*. The streams have here incised their channels below the level of the plains and the so-called Cerro is simply a projecting bluff overlooking the river. This locality has been marked by Prof. Walther by the erection of a stone in commemoration of Darwin's visit in 1833. There is, however, a considerable difference between the height of the river-bank, 30-35 m. according to Walther*, and that of the cliffs of Perika, about 50 ft. according to Darwin*. also in the composition of the lower part of the cliffs as recorded respectively by Walther and Darwin. It is thus permissible to doubt whether the actual section described by Darwin has yet been recognized. It is certain, however, that the river bank in this locality was Darwin's "farthest north" in Uruguay, and it was an admirable thought and a graceful tribute on the part of Prof. Walther to mark out a "Rincón Darwin" and to give the name of "Darwin Cliff" to the Cerro de los Claveles in recognition of "the importance of the geological observations initiated by the great British scientist"†.

Some play has been made of recent years in local scientific circles over the alleged polemic between Darwin and D'Orbigny about the occurrence at Punta Gorda beneath well-defined Tertiary strata (Entrerriano) "in the vertical cliff, nearly on a level with the river" of "a bed of red mud absolutely like the Pampean deposit, with numerous often large concretions of perfectly characterized white, compact toska-rock"‡. D'Orbigny, who had preceded Darwin in South America and to whom Darwin was much indebted for examining and naming his molluscan fossils, had not seen the section at Punta Gorda during his sojourn in Uruguay and Argentina in the years 1826-29, but he had stated that he was unwilling to believe that beds of the same nature with the Pampean formation ever underlie the ancient marine Tertiary strata§. He maintained that there could be no analogy between the lower beds at Punta Gorda, which were of marine origin, and the Pampean clay, which was of quite a different character "déposée dans un laps de temps très-court, comme le résultat d'une grande commotion terrestre"¶. Darwin steadily refused to accept this hypothesis and insisted that "from whatever source and through whatever means the great

Pampean formation originated, we here have unequivocal evidence of a similar action at a period before that of the deposition of the marine Tertiary strata"‡.

The incident left an unpleasant flavour which has not yet been dispelled. Difficulties of investigation and comparison, of translation and re-translation, keep the controversy alive, while almost every author who visits the locality provides a different interpretation. Kraglievich of Buenos Aires, now deceased, who knew the red mud of Punta Gorda, said that "its nature is not entirely equal to that of the true Pampean of Argentina, . . . being much more similar to the clay and loessitic sandstone of Uruguay"‡. Windhausen, also deceased, considered this sufficiently confirmative of Darwin's observation of a continental layer beneath the marine Tertiary beds‡. Prof. Walther supports D'Orbigny, and represents Darwin as having fallen into error§. He admits that at first sight the character of the rock at Punta Gorda is "loessoid or similar to Pampean clay"‡, but asserts that there is a distinct petrographical difference between the two deposits. This has been investigated by Frengelli‡, who states that under the microscope the Punta Gorda clay is almost entirely composed of particles of volcanic glass with grains of sand scantily accessory, while in the Pampean clays the volcanic material is accessory to fine sand and silt. Thus it would appear that volcanic dust which falls on the pampas at the present day fell sometimes much more abundantly in the same region in past ages, and that there is accordingly every justification for Darwin's suggestion of the recurrence of similar conditions during the accumulation of the great Pampean formation.

While, therefore, it is clear that in respect of Punta Gorda, Darwin cannot reasonably be accused of any serious error of observation, those of us who know something of the country he traversed will readily agree with Prof. Walther in admiring the fact that, in a hurried journey of fourteen days, he was able to recognize certain details of geological structure the significance and importance of which are still being debated by lesser minds after the lapse of a hundred years.

Obituary Notices

Prof. H. E. Armstrong, F.R.S.

HENRY EDWARD ARMSTRONG, whose death on July 13 in his ninetieth year we regret to announce, was born on May 6, 1848, in Lewisham, where he lived all his life. Of the influences during his early youth which inclined him to chemistry, little is known, but when he left Colfe's Grammar School at Lewisham his father, acting on the advice of an engineering friend, allowed him to become a student at the Royal College of Chemistry, Oxford Street, in the summer term of 1865, actually Hofmann's last term before his departure for Berlin. Chemistry was the only subject taught, but the College was affiliated to the Royal School of Mines, then housed in Jermyn Street. A free lance, he attended such courses at the two institutions as he thought fit including among them those given by Tyndall, Huxley and Ramsay, being also for some unexplained reason an almost regular attendant on Saturdays at the operating theatre of St. Bartholomew's Hospital. This roving quest came to an end when Frazerland, who had followed Hofmann as professor and, towards the close of 1866, had been appointed with two other members a Royal Commission to inquire into the pollution of rivers in Great Britain, took him into the private laboratory, where together they developed the combustion *in vacuo* method of water analysis, which played so important a part in the campaign for ensuring the safety of the domestic water supplies of the country.

In October 1868, while yet young and impressionable, Armstrong went to Leipzig to work under Kolbe, an inspiring teacher, but remembered also as an unsparing and provocative critic. Graduating Ph.D. after five semesters, he returned to work with Matthiessen on alkaloids at St. Bartholomew's Hospital Medical School and, during the next twelve years, had charge of the chemistry classes for medical students preparing for the London degree; his appointment as professor of chemistry at the London Institution, Finsbury Square, followed a few months later. An earlier occupant of the chair had been Sir George Grove, inventor of the unpolarizable Grove cell and the hydrogen-oxygen gas battery: Armstrong's interest in the general problem of chemical interchange, and particularly of the part played by the depolariser, can be dated from his discovery of specimens of the battery in the Institution's laboratory and the purchase of a copy of Grove's memoirs.

Armstrong's next appointment was that of professor of chemistry in the City and Guilds of London Institute for the Advancement of Technical Education, founded in 1878, but until the Finsbury Technical College was ready for occupation in 1883, the work of his department had to be carried on during four years in temporary quarters at the Cowper Street Schools, Finsbury. A year later he was translated to the newly erected City and Guilds

College, South Kensington, where a novel type of institution came into being, self-governed academically by its four professors—chemistry, engineering, mathematics and physics—and independent of external examiners, which rapidly grew to be recognized as a great professional school of engineering. But in 1911, when the City and Guilds College by incorporation became the engineering section of the Imperial College of Science and Technology, its chemistry and mathematics departments were closed down, although provision was made for chemistry diploma students to finish their course under Armstrong's supervision—with its completion, chemistry ceased to be taught in the City and Guilds College, and the last of the laboratories of the department was dismantled in 1914.

The submergence of the chemistry department involved also the closing down of its crystallography laboratory, the only one in Britain, after an existence of rather more than a quarter of a century. Convinced that the most certain method of identifying a substance was to be found in its crystalline form, Armstrong in 1886 determined that, as an essential part of their training, diploma students in chemistry should measure any new crystalline substances they might prepare which were suitable for the purpose. To this end a course of laboratory instruction was arranged by Mr. H. A. (now Sir Henry) Miers, and under his direction and that of Pope and of Lowry who succeeded him, a wealth of material was accumulated, which led to the publication by Armstrong, conjointly with Colgate and Rodd, of a series of papers under the title "Morphological Studies of Benzene Derivatives" in the *Proceedings of the Royal Society* during 1910–14.

Thus ended an interesting and—if account be taken of the careers of students trained by its methods—a successful experiment in teaching chemistry on scientific, if unorthodox, lines. For Armstrong, such an ending was unrelieved tragedy. Thereafter, although a small suite of laboratories was placed at his service in the Royal College of Science building, it was no longer as an investigator but by controversy that his work as missionary for the propagation of the truth as he conceived it was carried on.

During the tenure of his chair at the London Institution, Armstrong maintained a steady output of research, but it was in an unexpected role that he first directed attention to himself. While working with medical students, but without previous training as a teacher, he—to use his own words—taught himself how to teach them chemistry and, aided by that effort, developed the system which became known as the heuristic method of teaching science experimentally in schools, in the advocacy of which, as opposed to the didactic method then followed, he never spared himself—or others—from the time he first championed the cause at the International

Conference on Education, convened in connexion with the Health Exhibition of 1884. In the paper submitted to the Conference, he outlined a constructive plan for training pupils "to observe and think and act with clearly defined purpose, the work being carried out with common materials and in relation to common phenomena". This scheme was elaborated in his contribution to the "Special Reports on Education" published by the Board of Education in 1888, and in the second report of the British Association Committee appointed in the same year "to inquire into and report on the methods of teaching chemistry in schools", whilst criticism of schoolmasters figured prominently in his addresses as president to the Chemical Society in 1894 and later to the Chemistry and Education Sections of the British Association. The heuristic method on the scale that Armstrong conceived it is dead: its fate could not be otherwise under an examination system—intensified since the widespread adoption of the School Certificate—which does not distinguish between the school and the academic outlook on science as a mental discipline.

Prior to the move to South Kensington, Armstrong had three major problems in chemistry continually in mind: the confusion about methods of determining constitution in the naphthalene series; the perplexing reactivities of camphor which served only to show the inadequacy of any formula for the substance based on the benzene model; and the mechanism of chemical change. Before his contribution to the elucidation of each is reviewed briefly, it should be mentioned that, as the College catered chiefly for engineers, the number of diploma students in chemistry was always small. Nevertheless, it was not long before the department as a school of research in organic chemistry attracted advanced workers from other institutions, doubtless in appreciation of Armstrong's pervading influence and a wise choice of members of his staff. He was constantly in the laboratory, his technical skill was always available when difficulties in manipulation arose, and his advice, encouragement, criticism and retentive memory never failed those who could benefit by them. If a measure of his stature as professor be desired, it may perhaps be gauged by the fact that, of those who worked under him as colleagues or pupils, not a few have achieved marked success in industry, whilst the others six either hold or have held university chairs and seven became fellows of the Royal Society.

The naphthalene research, resumed in 1886, in which Davis, Roemer, Lapworth and Wynne took part, was concerned with the bromination, nitration and sulphonation of the hydrocarbon and of its halogen and hydroxy derivatives and included a study of the mechanism of nitration; the investigation of many cases among sulphonic acids of the transference ('isomeric change') of the sulphonic group from one position to another within the molecule; and the preparation and identification of the complete number of di- and tri-chloronaphthalenes theoretically possible—ten and fourteen respectively—by reference to which the structure of any di- or tri-derivative of the

hydrocarbon could be ascertained beyond doubt. Incidentally, it may be mentioned that Armstrong's series of papers embodying evidence for his view that carbon compounds exhibiting colour are quinone-like in structure belongs also to this period.

Towards the solution of the problem of the constitution of camphor from the analytical side, Armstrong and his collaborators made many important contributions. With Miller in the early 'eighties, he identified no fewer than four C_{12} homologues of benzene in the products of the action of sulphuric acid and other dehydrating agents on the substance. Then he and Kipping, who joined the staff in 1891, investigated 'camphren', an oxygenated product of the interaction with the acid—an inquiry which led Kipping jointly with Pope to discover how to sulphonate, rather than to dehydrate, camphor and to unravel the intricate isomerism of the camphor-sulphonic acids thus obtained. Important, too, was the identification of the three positions in which substitution occurs in the camphor molecule: this followed from the investigations of Kipping and Pope for the π -derivatives and of Armstrong and Lowry for the α - and β -derivatives. It was while studying the nitration of dibromocamphor at the College that Forster's interest in camphor chemistry was kindled and there, too, that Lowry's study of the mutarotation of nitrocamphor in various solvents proved that 'isomeric change' is not spontaneous but dependent on the presence of a catalyst.

Armstrong's unwavering advocacy of Faraday's view that "ordinary chemical actions . . . are themselves electrical" led him to define "chemical action as reversed electrolysis". The arguments by which this thesis was defended are to be found in the presidential addresses to the Chemistry Section of the British Association at Aberdeen in 1885 and Winnipeg in 1910; the presidential address to the Chemical Society in 1895; and in frequent contributions to ephemeral literature during the last half century. From first to last he never ceased to urge the view that solution is in effect a manifestation of chemical activity, the production of an electrolyte in aqueous solution being dependent on the combination of solvent and solute. Hence the prolonged controversy with Arrhenius (and Ostwald) whose theory of electrolytic dissociation in solution he regarded not only as unnecessary but erroneous—to be denounced with almost religious fervour as a chemical heresy. Although the Arrhenius conception has lent itself to modification, predicated among its later developments association of the ions of the solute with the solvent, and in its primitive form is now mainly of historical interest, the hydrate theory of solution has not emerged from the merely qualitative stage and involves too many unverifiable assumptions to make headway. Armstrong's experimental contribution to the discussion, in which Caldwell, Eyre, Worley and others assisted, is to be found in the thirty-two papers published during the period 1906–14 in the *Proceedings of the Royal Society* under the title "Processes Operative in Solution", the sixth of which gave, in 1908, the most complete statement of his theoretical views.

A few years earlier than, but parallel with, this inquiry into the nature of solution, Armstrong's interest in biological problems, never long in abeyance, led to an equally protracted study of the nature and mode of action of enzymes being undertaken under his guidance, about which, when it was begun, little exact information was available. In the first eight of the twenty-three papers, all of which save the first are to be found in the *Proceedings of the Royal Society*, E. F. Armstrong (Salters' Company's research fellow at the College, 1902-5) showed quantitatively that the action of sucrorclastic enzymes as hydrolytic agents is controlled or retarded by the products to which they give rise and that from glucose by interaction with maltase, isomaltose, but with emulsin, maltose is synthesized. Later, the two Armstrongs with Horton isolated a β -glucase (prunase) both from the mixture of enzymes known as emulsin, and, more readily, from various species of *Prunus*, which was used by them to ascertain the distribution of cyanophoric glucosides in a variety of herbage plants and its variation with locality and season. Mention, too, must be made of the elder Armstrong's investigation of the activities of urease, linase and lipase—including the synthesis of fats by the aid of the last-named—carried out in conjunction with Caldwell, Eyre, Gooney and Horton among others which led to the conclusion that action takes place wholly at the surface of the colloidal particles of the enzyme in suspension—not between substances in solution—the enzyme having the double function of attracting the hydrolyte and of determining its hydrolysis. Not the least interesting of the series was a paper by the Armstrongs on the action of chloroform, toluene and similar substances in stimulating enzymic action in living structures which they suggest may lead to an understanding of the physiological function of the esters, terpenes and scents secreted by plants and of anaesthetics.

Of the many educational and agricultural bodies with which he was associated, two in particular gave Armstrong much pleasure: he was appointed a member of the Council of Almoners of Christ's Hospital in 1896 on the nomination of the Royal Society, and, after many years as deputy chairman of the Committee of Education, became its chairman in 1930, holding office until his health failed; and he represented the Chemical Society on the Lawes Agricultural Trust Committee at Rothamsted from its inception in 1889, becoming its vice-chairman in 1918 and its chairman so recently as last May. Frequently of late years in addresses and in articles from his pen, the national importance of pure (non-pasteurized) milk, natural foods and honest beer was urged as also the improvement of grass and other crops necessary for their production. His last public speech was made at a 'barley' meeting of farmers at Warminster in July 1936.

Fond of the open country and a frequent traveller abroad in middle life as Armstrong was, Borrowdale in spring and autumn became for many years his beloved holiday resort. Field geology was one of his hobbies: he was for many years a member of the Geologists' Association, and photographed the chalk

from Yorkshire to Dorset to supply the illustration for the monographs on this formation prepared by the late Dr. Rowe of Margate. Another was his garden, and in the unrivalled colours of flowers he found the utmost pleasure: the æsthetic side of his nature found its satisfaction, too, in other ways—he was an enthusiastic opera-goer and a discriminating lover of pictures. Let it be added that no account of his life would be complete without a tribute to the memory of his wife, whose serenity and comprehending sympathy during the fifty-eight years of their married life were to him boons ever gratefully acknowledged.

Armstrong was *doyen* of the Royal Society, having been elected to the fellowship in 1876; he had been a fellow of the Chemical Society since 1870, one of its honorary secretaries during eighteen years, and its president during two; LL.D. of St. Andrews, D.Sc. of Melbourne and Madrid; honorary livery man of the Leathersellers' Company; Davy medallist of the Royal Society; Albert medallist of the Royal Society of Arts; Messel medallist of the Society of Chemical Industry; and Horace Brown medallist of the Institute of Brewing.

Temperamentally, Armstrong allowed feeling to influence his judgment to a degree unusual in an exponent of experimental science. Few of his speeches and writings were free from this intrusion: in his view, as expressed in the article "Chemistry" in the thirteenth edition of the "Encyclopædia Britannica" (1926), "Chemistry however is an art as much as a science and the chemist is full of feeling which cannot be quantified". Essentially an individualist, he did not find it easy to co-operate with others even for causes that aroused his enthusiasm and, if "apostolic blows and knocks" were not forgotten in the advocacy of his views, an autobiographical note in a recent article (1932) is not without significance: "Somewhat arrogant and extreme perhaps in his denunciation"—the opinion passed by George Eliot on Savonarola in the poem to Romola—will probably be the criticism passed on me by my friends. The situation is saved by her remark 'But a *Frater* *predicator*, who wanted to move the people, how could he be moderate?' " Nevertheless, those who knew only this side of Armstrong failed to recognize that these were but the defects of his qualities. Lacking his disinterestedness, his essential goodness of heart and his idealism, he could not have won and kept the good-humoured acceptance as an institution which became his in the post-War years. The attitude of mentor, the wounding criticism from a too facile pen: these need not be remembered now—rather we have to mourn the passing of a man whose devotion to chemistry, not least in its social implications, was the master passion of his life. W. P. W.

We regret to announce the following deaths:

Prof. Percy Gardner, emeritus professor of classical archaeology in the University of Oxford, on July 17, aged ninety years.

The Marchese Marconi, on July 20, aged sixty-three years.

News and Views

Long Distance Air Record

THE Russian pilot, Colonel Michael Gromoff, with two companions, flying an Ant 25-1, landed at San Jacinto, California, on July 14—a flight estimated to be of about 6,625 miles from Moscow, over the North Pole which lasted 61 hours 7 minutes. The existing record of 5,675 miles, was held by the French airmen Codos and Rossi. The Soviet Government has been interested in this route, which follows practically a direct line across the North Pole. The pilot's log mentions the points Moscow, south-west Novaya Zemlya, North Pole, northern British Columbia, Oregon, San Francisco, and San Jacinto. So recently as last June, Chkaloff with two others on a similar machine flew over the same course, reaching Portland, Washington, a distance of 5,600 miles. The machine, also an Ant 25-1, was specially fitted for long-distance work, carrying extra fuel tanks and liquid oxygen, presumably for flying at considerable altitudes. The total loaded weight of the machine was $11\frac{1}{2}$ tons, about 6 tons of which is stated to have been fuel for the flight.

ONE result of this flight, although possibly of a negative order, is the confirmation of the fact that the severe storms encountered, added to many hundreds of miles of ice-bound regions in which forced landings would be impossible, make it questionable as to whether such a route can ever be a commercial possibility, even though it may be the shortest distance from northern Europe to North America. Apart from this, such flights have an obvious interest to the Russian authorities, whose internal air transport and military defence problems over the long distances in northern Siberia, are of a very similar nature. Colonel Gromoff is a well-known Russian test pilot, who has been connected with the development of Russian aviation since about 1917. His name has been particularly associated with the principal Russian research station, the Moscow Central Aerodynamic Institute. It is interesting to remember that he broke a world record in 1934 with a continuous flight of 7,765 miles in a closed circuit.

Commercial Production of Oil from Coal

ON July 14, the House of Lords debated a Motion by Lord Mottistone that plant for obtaining oil from coal should be set up in Durham and South Wales in the interests both of national defence and increase of employment. Lord McGowan said that the experience of Imperial Chemical Industries, Ltd., has established the technical possibility of such processes but at capital and operating costs so high that the process, even with the assistance of existing protection, is not attractive to private capital. Success would have to depend not on private initiative, but on Government policy. The production of heavy oil for marine purposes from coal is at present un-

economical. The effect on employment ought not to be exaggerated. A plant capable of producing 150,000 tons of petrol annually provides work for 6,000 persons of whom 2,500 would be miners. Low-temperature carbonization and hydrogenation are complementary processes, and increased use of smokeless household fuels would promote both national security and national welfare. Hydrogenation processes, he emphasized, are a question of high national policy and beyond the purview of an ordinary limited liability company. Reference was made to the Fischer process and other methods of developing the use of coal. Lord Hutchinson, in reply, said the Government is awaiting the report of Lord Falmouth's Committee before deciding its policy for the production of oil from coal. Meanwhile, it is encouraging the establishment of plant for carbonizing coal at low temperatures, and another will be in production in South Wales next year.

Observations of the Longest Eclipse

INFORMATION has come to hand of the success of Prof. J. Q. Stewart, of Princeton University, and Mr. T. Stokley, director of the Planetarium in Philadelphia (representing the Franklin Institute and the Cook Observatory), in observing the recent total solar eclipse for an uninterrupted period of 7 min. 6 sec. from the S.S. *Steelmaker* of the Isthmian Steamship Co. The ship was at $133^{\circ} 38' W.$, $9^{\circ} 49.5' N.$ and the sun's altitude was $75^{\circ} 8'$. Owing to the ship's motion, totality lasted an extra four seconds for the observers. Prof. Stewart was engaged in visual study of the corona, while Mr. Stokley took photographs of the corona and measures of its total brightness at mid-eclipse. Preliminary measures show that this was of the same order as that of the full moon, while the observers on Canton Island have reported a value about half the full moon. The difference is in the opposite sense to what would be expected from purely geometrical considerations of the amount of low corona uncovered. The eclipse is described as a bright one. Despite the shadow extending around in all directions for seventy-seven miles, there was no need of flashlights to read the instruments, while ordinary newspaper print could be read with ease. Only Venus, Mercury and a few first magnitude stars could be seen, and there was indication of a high layer of haze in the sky. The corona was of late intermediate type, approaching maximum, made up of radial spikes and with no very long streamers.

Price Chair of International Economics

THE Council of the Royal Institute of International Affairs announces the appointment of Prof. Allan G. B. Fisher, of the University of Western Australia, to the newly established Price chair of international economics at Chatham House. The purposes of the chair is to provide the Institute with the means for

more intensive research into world economic problems than has hitherto been possible. Prof. Fisher is the first occupant of this chair, and will consequently inaugurate the new development in the Institute's activities which has been rendered possible by the recent generous gift of £20,000 made by Sir Henry Price for this specific purpose. Prof. Fisher, who was born at Christchurch, New Zealand, in 1895, has been professor of economics in the University of Western Australia since the beginning of 1936. He has contributed widely to periodicals dealing with economics, and has published two books, "Some Problems of Wages and their Regulation in Great Britain since 1918", and "The Clash of Progress and Security". Prof. Fisher hopes to take up his new post at Chatham House early in 1938.

Avebury

Two years ago, Mr. W. G. A. Ormsby-Gore, then First Commissioner of Works, urgently directed attention to the necessity of taking steps by means of a planning scheme to preserve the surroundings of Avebury, constituting in their entirety, as he pointed out, the most imposing monument of prehistoric civilization in the whole world. He then expressed the hope that it would not be long before such a scheme was initiated. There is now a prospect that this hope may be fulfilled. A scheme under the Town and Country Planning Act, 1932, has been prepared, which, if the necessary financial provision is made, will be put into operation before the main Wiltshire Planning Scheme, for the planning and preservation of the village of Avebury and its immediate surroundings. This scheme involves the prohibition of building in certain areas, and its restriction in others. The area covered by the prehistoric remains will be preserved for ever from building, and this, with the willing co-operation of the owner, also applies to the grounds and building of the Manor House, of which part dates from before 1648, part from the latter half of the sixteenth century. Over the main part of the downland, upon which the charm of the monuments and their appeal to the historic imagination so intimately depend, no new building will be allowed, except for agricultural purposes and necessary extensions of existing buildings, while the harmonious character of new cottages will be ensured and the planting of trees continued. To some small extent the village has encroached on the monument, but condemned cottages will not be re-erected. The agricultural character of the district will be preserved, and provision made for its future prosperity by the setting aside of adequate sites for new buildings.

This scheme will cost money. It is estimated that a sum of £11,000 will be required to meet the cost of compensation and other charges necessary to carry out the provisions of the scheme. Towards this, the sum of £4,000 already has been promised privately. An appeal for the balance is made by Sir Ernest Wills, Lord Lieutenant of Wiltshire, the Marquess of Bath, chairman of the County Council, Sir Philip

Sassoon, First Commissioner of Works, Mr. W. G. A. Ormsby-Gore, Lord Baldwin and others. The National Trust has undertaken to receive subscriptions and hold the funds for the purpose of the Scheme, which will be controlled partly by a special body composed of representatives of the County Council, the Rural District Council, the Parish Council, H.M. Office of Works, the Council for the Preservation of Rural England, and the Wiltshire Archaeological and Natural History Society, and partly by the National Trust. In view of the number of prehistoric monuments of the first importance in the neighbourhood of Avebury—Windmill Hill, Silbury Hill, Overton Hill, the Avenue, the Roman Road, to name the most prominent only—the price of preservation is small, and the appeal should meet with a ready response from the public.

Mesolithic Site in Surrey

An important mesolithic site consisting of a group of pit-dwellings has been excavated by Dr. J. G. D. Clark near Farnham, Surrey. It was discovered by Mr. W. F. Rankine, a local archaeologist, and has been described as "without any parallel in this country". (*The Times*, July 20.) The pits are circular and some three feet deep by about twelve feet across. One of the dwellings shows the site of a hearth, in which the blackening by fire can still be seen. Several hundred microlithic implements have been found, as well as a fine pointed-butt axe or pick, about five inches long. It is suggested that the settlement may be dated at about 3000 B.C., that is towards the close of the Mesolithic period, to which Dr. Clark in his studies of the Mesolithic period in Northern Europe has assigned a dating of from 8000 B.C. to 2500 B.C., when the full-fledged Neolithic culture takes its place. It would appear that this find gives an entirely new conception of the character of the mode of life of the Mesolithic peoples, which here at least would appear to have entered on a more or less settled stage. Other sites previously investigated afford little or no indications of permanent habitations, the inhabitants having lived in shelters, wind screens or skin tents as did the prehistoric inhabitants of North America and the less advanced of the recent Indians.

Necessities of Scientific Training

In his presidential address delivered at Harrogate on July 6 to the Society of Chemical Industry, Lord Leverhulme emphasized the value of a scientific training whether a man's business career is on the technical side of industry or not. Scientific method and the scientific habit of thought have an application far beyond the confines of technical research and technical processes, and Lord Leverhulme referred in particular to the importance and value of a scientific study of markets involved in market research and forecasting, as well as to the development of scientific methods of management commencing with the ideas and methods of Taylor. Referring to the synthetic production of an increasing number of our raw materials, he suggested that this development indicates an economic revolution, the proximity and

scope of which are as yet insufficiently appreciated and that the time is not far distant when man, largely independent of the accident of geographical or climatic environment, will rely very considerably on the chemist to provide substitutes. The chemist is a brilliant example of the truth that scientific research leads through the elimination of waste to the conservation of resources. In an age of industrial research directed to the production of immediately practical results, the question arises whether, in the highly developed sciences, we have gone too far in the direction of intensive scientific research with the object of gaining immediate benefits at the expense of more general research in the less developed sciences which might ultimately yield social benefits of no less value, though more remote. Lord Leverhulme suggested that if the law of diminishing returns operates in scientific research, it might well be better to devote more of our resources to the less developed and less immediately profitable sciences.

Chemistry, Past and Present

IN Prof. G. G. Henderson's absence, owing to the death of Mrs. Henderson, his medallist's address at Harrogate on July 6 to the Society of Chemical Industry, "A Retrospect of Chemical Science," was read by his colleague at Glasgow, Dr. D. T. Gibson. Prof. Henderson, an original member of the Society, who in 1888 was responsible for organizing the first annual meeting in Glasgow, reviewed developments in chemistry in the last sixty years, including present-day tendencies, and in referring to post-War advances in applied chemistry in Great Britain, commented on the increasing demand for the services of chemists not only by chemical industries but also by many other industries, and on the marked appreciation of the importance of chemical research. In particular, he referred to the importance of the contribution of the chemical engineer in the development of chemical industries, as indicated by the provision of facilities for his training, and the foundation of the Institution of Chemical Engineers and of the Chemical Engineering Group of the Society. The future prosperity of Great Britain, Prof. Henderson urged, largely depends on the support given to the progress of science and especially of chemistry, and in this matter a united profession is of the utmost importance if its influence on public opinion or on Government departments is to be effective. For this reason, he pleaded for generous support of the Chemical Council and the scheme for a Chemistry House, and in particular urged that important firms employing considerable numbers of chemists should do more to encourage their staffs to become individual members of at least one of the publishing societies.

"Applied Anthropology"

IN view of the frequency with which, it is now generally recognized, problems of administration among backward peoples are intimately bound up with matters of belief and custom, and give rise to problems of which the many ramifications cannot be understood, or perhaps even perceived, without

anthropological study, or upon which it may be necessary to seek the advice of the expert anthropologist, an announcement made by the Royal Anthropological Institute is both welcome and opportune. The Council of the Institute, it is stated, has appointed a Standing Committee on Applied Anthropology, which will meet at regular intervals for the discussion of problems of culture contact and the application of anthropological knowledge to the government of subject races. The Committee will seek to stimulate popular and official interest through the publications of the Institute, representations to Colonial Governments through the Colonial Office, and personal contacts with officials. It will also endeavour to further the organization and systematization of research in this field by means of discussion within the Committee and with experts engaged in research, and by promoting field-work according to a considered plan. A programme of typical questions affecting administration and upon which further research is desirable, has already been drawn up. In view of the wide connexions of the Institute and its close relations with those having expert knowledge in every part of the Empire, the work of the Committee cannot fail to be of the greatest utility in promoting a wise and enlightened policy in the administration of the affairs of the less-advanced races for whom the Imperial Government is responsible.

Need for the Study of Human Biology

IN an address at the celebrations of centenary of the University of Michigan on June 17, Prof. Raymond Pearl emphasized the necessity of evolving a science of human biology broad enough to synthesize our knowledge of man's mental and spiritual nature as well as of his physical nature if civilization is to survive. Our rapid advance in material things, while in wisdom and goodness little or no advance has been made, renders our development so lopsided as to threaten a catastrophe. The data for the unification of human knowledge do not yet exist, and one of the main challenges of the present situation to the man of science is that by natural aptitude and training he is the best equipped to obtain such data. Prof. Pearl believes that the universities, rather than specially founded independent institutions, offer the best environment for scientific research, and the achievements of the last hundred years encourage the belief that progress will continue.

The Bournemouth Outbreak of Typhoid Fever

THE report of the late Dr. Vernon Shaw, on his investigations into the outbreak of enteric or typhoid fever that occurred in Bournemouth, Poole and Christchurch in August and September 1936, has been issued by the Ministry of Health (Reps. on Pub. Health and Med. Subjects, No. 81. London: H.M. Stationery Office. 9d. net). The outbreak was first brought to the notice of the Ministry on August 21, 1936, and Dr. Shaw began his investigations the following day. He was informed that thirty cases of enteric fever had been notified during the preceding

twenty-four hours, and that a number of other patients, scattered throughout the three towns, were under observation. The only factor common to all the patients was the consumption of raw milk retailed by one distributor. It was concluded that the milk was infective for a period of about thirty-one days preceding August 22, and the approximate number of persons who contracted the disease was 718, of whom 518 were residents, and of these fifty-one died. No source of infection could be discovered among those distributing the milk, nor at the retailer's depot. The supply was collected from thirty-seven farms scattered throughout a large part of Dorset. Dr. Shaw was satisfied that the outbreak was due to the consumption of raw milk, and that the dealer's supply was infected by the contributions of one or possibly two producers whose milk in turn was infected by water from a contaminated stream. Immediately the outbreak was recognized, the distributor, acting on Dr. Shaw's advice, pasteurized the whole of his supply, and no unpasteurized milk was distributed after the morning round on August 22. This measure was immediately successful in terminating the outbreak.

Poetry and Astronomy

DR. F. W. Grover, professor of electrical engineering, Union College, Schenectady, N.Y., has contributed to the *Scientific Monthly* of June an article in which are brought together a number of striking passages in poetry referring to astronomical objects and phenomena. Milton, Dante, Tennyson and Longfellow are naturally given the chief prominence in these extracts, but there are also beautiful passages from Browning, Housman and others. Dr. Grover refers appreciatively to Mr. Alfred Noyes's "Watchers of the Sky", but wonders why the new knowledge of the starry heavens makes so small an appeal to contemporary poets, whose fancies rarely stray into this virgin field. "Yet," he says, "it would be a fascinating task, and one demanding no mean ability, to picture the whirl of the spectroscopic binaries, and the rhythmic oscillation of the Cepheid variables, to describe the individualities of the giant and dwarf stars, or to soar in imagination to the confines of an expanding universe."

Progress in Gliding

RECENT numbers of the *Sailplane and Glider*, the official organ of the British Gliding Association, give evidence not only of the advances that have been made in the technique of motorless flight, but also of the scientific knowledge that is producing. The development of aeroplanes has been so spectacular that development of sailplanes may be overlooked. But these have attained an airspeed of 87 m.p.h., a straight line distance of 813 miles and a height of more than 19,000 feet; records all beyond those of power planes in 1911. It has long been a reproach that sailplanes were dependent on hills and winds; but an effort was made last June to meet this by the organisation of a cross-country circular tour. A definite route of 415 miles, beginning and ending at

Darmstadt, was laid out, the time allowed being ten days and each separate flight was to start with an aeroplane tow to not more than 500 metres. Of the eight pilots who got away, four completed the course in the time, the first taking only seven days. The use of 'thermals'—ascending currents apart from clouds—has become more widespread. Of late, at four or five English gliding centres, pilots have been pulled up to a few hundred feet by a winch and have got away without any help from the wind or from a hill.

On the scientific side, the practice of soaring inside clouds, as well as the use of thermal currents and of cold fronts, has given valuable meteorological knowledge. Soaring in clouds not infrequently proves adventurous. Last June, for example, a German pilot went into a cloud to gain height and his rate of ascent increased from 4 m. a second to beyond what his variometer would register. When he was at 16,400 feet he tried in vain to get out of the cloud; he was tossed up and down, thoroughly chilled and bombarded with hail; the climax came when a wing broke off. However, the pilot with difficulty got clear, and descended to safety in his parachute. Naturally those who take such risks want to learn all they can about the conditions; and while some carry special recording instruments, others work out the paths of air in thermals or make and study fast-motion cloud pictures. As an illustration of the data brought by such means may be quoted the records of pressure, temperature and humidity obtained during a flight from the Chiemsee across the Tyrolean Alps into Italy; the pilot rose to 10,800 feet to cross the Gross Venediger. Meteorologists doubtless have shrewd ideas as to what goes on in such places as cloud-cells and lenticular clouds; but there, as well as in many other regions, definite observations must have the highest possible value.

Monthly Meteorological Elements

IN the *Meteorological Magazine* of June there is a new feature that has been developed as a result of a proposal made by Prof. A. Wagner at the International Meteorological Conference at Copenhagen in 1929, that monthly mean values of various meteorological elements should be broadcast as soon as possible after the end of each month for selected meteorological stations. The arrangements for carrying out this proposal were completed and ratified at the Warsaw Conference in 1935, and provided for the inclusion in the broadcasts of mean pressure in millibars or millibars and tenths of a millibar, mean temperature in degrees and tenths, total rainfall in centimetres, and, for certain places, resultant air transport for the month. Since the first broadcasts were made in June 1936, the selected stations have increased in number, and data for Russia, Siberia and America are now included. The figures for May 1937, except those for air transport, have been discussed in the journal mentioned above, pressure and temperature being plotted so as to show cartographically the main features of those elements of the weather for that month over a large part of the northern

hemisphere. The interesting fact emerges that the excess of temperature above the average for 1901-30 in the British Isles, which ranged from 1° to 3° F., was also experienced throughout Europe and the greater part of North America, the excess being more than 5° F. over the north-east of Europe, most of Scandinavia and northern Canada and part at least of the Nile valley. The warmth of Europe and North America is seen to be associated with, if not due to, a lowering of mean pressure in the arctic regions and Siberia, combined with an excess of pressure over most of Europe, the United States and southern Canada. This information was available at the Meteorological Office within seven days of the conclusion of the month under review.

Wear of Motor-Car Engine Cylinders

THE problem of cylinder wear has now become very serious in commercial and public service vehicles, according to an article in the January issue of the *Nickel Bulletin*. This is due to the new designs giving higher efficiency, and also the use of aluminium pistons. Wear is considered to be due to a combination of two causes: mechanical abrasion and the corrosive attack of the cylinder walls by the products of combustion. The former predominates in vehicles running for long periods with a hot engine such as motor-buses used for long-distance runs in daily service. The latter effect is the more important for vehicles which run intermittently with long waits between runs, like delivery vehicles. In these the engines never get properly warm. The development of nickel cast iron has provided a satisfactory solution. The addition of one or two per cent of nickel to a suitable composition of base iron has produced cylinder castings which are readily machinable and yet have a high Brinell hardness. Recently the manufacturers of many commercial vehicles have obtained excellent results by using heavily alloyed iron. The cylinders of both petrol and Diesel vehicles are now being regularly made of irons containing 4-5 per cent of nickel with or without proportions of chromium and molybdenum. Improved machinability is obtained by slowly cooling the castings from a temperature of about 650° C. When this course is followed, the original hardness is restored after machining by air-cooling the material from a temperature of about 850° C. In France, this hard type of iron has been used for several years with satisfactory results for air-cooled motor-cycle cylinders.

International Union of Biological Sciences

PROF. M. J. SIKS (Wageningen, Netherlands), secretary of the above Union, reports that the next General Assembly will probably be held in July 1940 at Stockholm immediately before the seventh International Botanical Congress. The president is Prof. E. D. Merrill (Harvard) and the vice-president, Prof. D. M. S. Watson (London). The report in *NATURE* (136, 612; 1935) on the International Botanical Congress at Amsterdam in September 1935 referred to the establishment of a liaison between the Congress and the Union. Dr. F. Verdoorn (Leyden), secretary

of the Botanical Section of the Union, reports on the work of this Section, which was deputed to execute the resolutions passed by the Congress and to assist the various commissions and committees then appointed. He reports that an index of current plant science periodicals, prepared by the Commission for Documentation, will be issued during 1937, and that the Commission for Urgent Taxonomic Needs is preparing an "Index Herbariorum". Suggestions or questions bearing on botanical nomenclature should be sent to Dr. T. A. Sprague, Royal Botanic Gardens, Kew, secretary of the Commission of Nomenclature.

Scientific Annual Publications: New ASLIB List

A SIXTEEN-page booklet has been issued by the Association of Special Libraries and Information Bureaux as a supplement to the ASLIB Book List, containing classified particulars of 212 recommended annual publications of scientific and technical interest, published in the English language. The publications are arranged by subjects, and include representative U.S.A. publications as well as those of the League of Nations and many of H.M. Government reports, etc., which are not often found in Press guides. The list should be of considerable service to information officers and those in charge of reference libraries or intelligence departments. The List can be obtained from the Association of Special Libraries and Information Bureaux, 31 Museum Street, W.C.1, at a charge of 2s. per copy to subscribers to the ASLIB Book List and 3s. 6d. to non-subscribers.

International Congress of Anthropological Sciences

ARRANGEMENTS are now announced for the second International Congress of Anthropological and Ethnological Sciences to be held at Copenhagen on August 1-6, in accordance with the decision taken at the first congress in London in 1934. It will be under the patronage of H.M. the King of Denmark and Iceland. The Congress will meet in seven sections, covering respectively physical anthropology, psychology, demography, ethnology, ethnography in six sub-sections according to geographical areas, sociology and religion, and linguistics and writing. Arrangements have been made for exhibitions and demonstrations in connexion with the subjects to be discussed, among them anthropological material of the Eskimo and Scandinavians of Greenland in the Middle Ages, and from the prehistoric burials of Denmark, and the skulls of Lagoa Santa, Brazil. There will be a demonstration of the relation of the ancient dwellings of Denmark and the structural systems of prehistoric times, which will take place at the Lyngby Folk Museum, where there will also be an exhibition of Danish national dances, including those of the Faroe Islands. A collection will be on view of medieval Icelandic manuscripts referring to the discovery of Greenland and Vinland, as well as the manuscript of Pomo de Ayala on the Kingdom of the Incas and Peru, recently published by the Institut d'Ethnologie de Paris, and manuscripts of the Iranian Avesta. The Ethnographical Museum, which has been closed for several years for enlarge-

ment and is the oldest in Europe, having been founded in 1846, will be reopened to the public for the first time at the meeting of the Congress. At the close of the session, an excursion will be made through Denmark, on which visits will be paid to kitchen-middens, Megalithic tombs, tumuli of the bronze age, iron age fortifications, the new Viking ship recently discovered at Ladby, and other antiquities of the Middle Ages. Subscriptions (members 30 Danish crowns, associates 15 Kr.) may be addressed to the Treasurer of the Congress, Nationalmuseet, 10 Ny Vestergade, Copenhagen, K.

Seventeenth International Geological Congress

THE seventeenth International Geological Congress is being held in Moscow on July 20-30, as noted in NATURE of January 23, p. 143. Many tours for the delegates have been arranged; for this purpose guide-books have been prepared giving detailed descriptions of the routes, all the interesting outcrops of mineral strata, the deposits of useful minerals, etc., with maps, plans and sectional drawings. Every delegate has a set of twenty-eight guide-books, and a newly issued geological map of the Soviet Union; each tour is being conducted by a Soviet geologist. According to a report issued by the Soviet Union Year Book Press Service, 403 foreign delegates, representing forty-six different countries, are attending the Congress; they include 139 from the United States, 50 from Great Britain, 33 from France, 20 from Japan and Manchukuo, 18 each from Germany and South Africa, and 11 from Sweden. Of Soviet geologists, 1,600 have intimated their desire to be present, but as many of them are at present engaged in field work, not all of them will be able to attend. The delegates will spend two days in Leningrad, where a session of the Congress will be held, and visits will be paid to the geological museums of the Mining Institute, the Central Institute of Scientific Research, the Arctic Institute, to give representatives of foreign countries an opportunity of becoming acquainted with the general characteristics of the mineral resources of the Soviet Union. In Moscow, the Congress will hold its sessions at the Observatory, where the institutes of the Academy of Sciences of the U.S.S.R. have also arranged an exhibition of collections relating to mineralogy, geochemistry and useful minerals, and the Palaeontological Institute is showing its collection of Perm vertebrates of the North Dvina Gallery. Among the subjects coming up for discussion at the Congress are: problems of oil and world oil resources; geology of coal deposits; the Pre-Cambrian system and its useful minerals; the Perm system and its stratigraphical arrangement; the inter-connexion of tectonic processes, magmatic formations and ore deposits; tectonic and geochemical problems of Asia; deposits of rare elements; geophysical methods in geology; geology of the Arctic and Antarctic.

Beit Fellowships for Scientific Research

THE Trustees have awarded Beit fellowships for scientific research, tenable at the Imperial College of

Science and Technology during the academic year 1937-38, as follows: extensions of fellowships already satisfactorily held for one year to Dr. N. Kemmer, for the continuation of his work on the theoretical studies in nuclear physics, under the direction of Prof. S. Chapman; and to E. K. Woodford, for the continuation of his research in plant physiology, the work to be done under the supervision of Prof. F. G. Gregory; new fellowships tenable for one year, but renewable for a second, to D. W. Goodall, for research on the physiology of the tomato plant, under the direction of Prof. F. G. Gregory; H. A. C. McKay, for an investigation of chemical problems by the radioactive indicator method, under the direction of Prof. J. C. Philip; A. K. Powell, for research on the various strains of *Heterodera Schachtii*, under the direction of Prof. J. W. Munro. The Trustees have also awarded a special Beit research scholarship to Dr. A. G. Gaydon, for research in spectroscopy under the direction of Prof. G. P. Thomson.

Announcements

GHEIMRAT PROF. ERICH LEBER, professor of surgery in the University of Munich, and the chief representative of plastic surgery in Germany, has been awarded the Goethe Medal for art and science on the occasion of his seventieth birthday.

THE sixth International Montessori Congress will be held in Copenhagen under the auspices of the Danish Minister of Education on August 1-10. Dr. Maria Montessori will give an address entitled "Educate for Peace". Further information can be obtained from the General Director, International Montessori Association, 1 Hampstead Hill Gardens, London, N.W.3.

ACCORDING to official reports, the birth-rate in Soviet Russia is steadily increasing. Last January, the number of births registered was 21.7 per cent higher than in January 1936, and in the first quarter of this year it was about 30 per cent higher than in the corresponding quarter of 1936. Of the Union republics the Ukraine records the largest increase for the quarter, namely, 70 per cent.

THE University of Reading proposes to reprint, in type similar to that of the original and accompanied by wood-cuts of the original drawings, the "Observations Anatomicae Selectiores Amstelodamensium", 1667-73. This work, the record of the observations of the Amsterdam School on the anatomy of seven mammals, four birds, the tortoise, the frog and thirteen fishes, is rare and its contents not widely known among biologists. Prof. F. J. Cole, to whom subscriptions for copies (1 guinea each) should be sent, is contributing a critical introduction.

ERRATUM.—In the announcement in NATURE of July 17, p. 104, of the award of the Johannes Schmidt Medal to Mr. H. G. Maurice the words 'thirteenth annual meeting' should have been 'thirtieth annual meeting'.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 158.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Packing Fractions of Krypton and Xenon

THE lines produced in mass spectra by hydrocarbon molecules have always played a predominant part in the accurate measurements of mass. This is particularly so in the use of the doublet method, since their high masses, due to the hydrogen, tend to provide easily resolvable doublets with ordinary atomic lines. With methane and ethane there is no difficulty in producing all the lines of the C_1 and C_2 groups, but when propane is used in a cylindrical discharge tube, only the first four lines of the C_2 group, 36, 37, 38 and 39, have a workable intensity. These were used in the measurements of the isotopes of chlorine¹. Fortunately, the lower pressure discharge in an eight-inch bulb gives all the lines up to C_2H_4 , though the even ones, 40, 42, 44, are weaker than the others. This has enabled comparisons to be made with the multiply charged lines of krypton and xenon, giving direct measurements of their packing fractions much more accurate than the indirect ones made ten years ago². The following are the results:

Doublet	Number of doublets measured	Difference in packing fraction	Difference of mass
$^{86}Kr++ - C_2H_2$	4	18.28 ± 0.2	0.0635
$^{84}Kr++ - C_2H_2$	19	20.20 ± 0.15	0.0828
$^{82}Kr++ - C_2H_2$	20	21.73 ± 0.15	0.0913
$^{80}Kr++ - C_2H_2$	18	23.10 ± 0.15	0.0993
$^{136}Xe+++ - C_2H_2$	14	20.16 ± 0.1	0.0867

Presence of traces of argon in the tube prevented any accurate determination of ^{86}Kr . Measurements of $^{136}Xe+++$ by the doublet at 44 were unsatisfactory owing to the presence of CO_2 , but its packing fraction appears to be nearly the same as that of ^{136}Xe , and is given provisionally.

The following are the packing fractions and isotopic weights deduced from values of hydrogen and carbon of 1.00812 and 12.00355 respectively:

Symbol	Packing fraction	Isotopic weight
^{86}Kr	- 7.30	77.9430 ± 0.0020
^{84}Kr	- 7.70	81.9369 ± 0.0015
^{82}Kr	- 7.60	83.9362 ± 0.0015
^{80}Kr	- 7.40	85.9363 ± 0.0015
^{136}Xe	- 4.46	128.9424 ± 0.0020
^{134}Xe	(- 4.4)	(131.942)

The Two Crystalline Modifications of Insulin

PROF. E. B. MATHEWS' first examination of Abel's crystalline insulin showed the presence of two types of insulin crystals¹. One of these, the so-called prismatic or needle variety, had marked birefringence and a development of faces strongly suggestive of rhombohedral symmetry, the crystals being elongated along the trigonal axis. Crystals of this type are commonly wedge-shaped, and very small wedge-shaped crystals have also been obtained by Scott² by crystallisation of insulin from acetate buffers at pH 5.2. The more common variety of insulin crystals are those obtained first by Abel³ from phosphate buffers at pH 6.2. These are very small flat rhombohedra appearing isotropic as usually viewed along the trigonal axis, but having actually positive birefringence. X-ray examination has here shown the presence of a simple rhombohedral unit cell⁴. It has been usual in the literature to describe these two forms—prismatic and rhombohedral—as polymorphic modifications⁵.

Through the kindness of Prof. F. L. Pyman, I have now had the opportunity of examining also insulin crystals of the prismatic type by the X-ray method. Two preparations were available. One of these consisted of very small crystals roughly wedge-shaped in outline and frequently twinned in cross forms as described by Mathews. As these crystals were only 0.05 mm. long and less than 0.01 mm. across, they could not be used for X-ray measurements. But there seems no doubt that the second preparation is identical with this, though here the crystals showed no identifiable faces. They were roughly needle-shaped masses up to 0.3 mm. long and rather less than 0.1 mm. in cross-section, extinguishing uniformly between crossed nicols and showing, as do the small wedge-shaped crystals, positive birefringence.

These needle-shaped crystals gave on X-ray examination photographs identical in the spacings and intensities of the X-ray reflections with those obtained from the original 'rhombohedral' crystals. The crystal structure is therefore the same in the two forms, and these are not polymorphic modifications though the change in habit is certainly very striking. Even here there is evidence that forms intermediate between the two varieties may occur. One sample of insulin, recrystallized from sodium dihydrogen phosphate and acetic acid, consisted very largely of small crystals showing nearly equal development of rhombohedral and prismatic (or more probably steep trapezohedral) faces, which gave them at first sight the appearance of rhombic dodecahedra. These crystals were much too small for X-ray examination, but the possession of positive birefringence combined with the symmetry leaves little doubt of their identity with the other two varieties.

In one respect only do the X-ray photographs of the needle crystals appreciably differ from those of the original rhombohedra. They all show a much more marked diffuse ring with a spacing of about 4.5 Å., a value we have come to consider characteristic of the presence of 'amorphous' proteins*. Here it may be due to imperfections of the crystal following perhaps partial breakdown. But amorphous proteins such as gelatin are known to have a marked effect on the habit of both organic and inorganic crystals; and it seems possible that a similar influence appears here, amorphous insulin or a breakdown product being included in the crystals and being itself responsible for the adoption of the prismatic form.

Absolute Configuration of the Naturally Occurring α Amino-Acids

THANKS largely to the extensive researches of Levene and his collaborators, it now appears to be well established that, as suggested by Clough in 1918¹, the naturally occurring α amino-acids all possess the same configuration. Until recently, the absolute configuration was not known for any optically active compound, but in the course of a theoretical calculation of rotatory power, Boys² deduced a rule giving the absolute configuration of any enantiomorph from the sense of its rotation—namely, "that a dextro compound has the configuration such that, when the largest group is nearest to the hypothetical observer the other groups in order of diminishing size appear in a clockwise rotation".

Fig. 1.

Boys's rule, which appears to have been accepted by Levene and Lowry, can only be applied with certainty in the absence of interactions of the solvent with the solute molecule, a condition which is far from being fulfilled by the amino-acids; marked solvent action is indicated in several cases by a complete change of sign of the rotation with temperature or with pH. The configurations of the amino-acids have, however, been correlated with those of

other compounds in which solvent action is less; from the recent paper of Levene and Mardashev³, the naturally occurring amino-acids have the configuration of laevo-rotatory 2-amino-hexane, a compound to which Boys's rule may be applied with more confidence.

If the validity of the rule and its applicability to this amine be accepted, then the naturally occurring α amino-acids, which amount to more than 95 per cent of most proteins, can be assigned the absolute configuration given in Fig. 1.

Use of Krypton-filled Ionization Chambers for Cosmic Ray Measurements

SOME years ago, compressed air and nitrogen were replaced by argon in cosmic ray ionization apparatus¹, argon being approximately twice as effective as nitrogen, which in turn is more effective than air.

Krypton is now used for filling special incandescent electric lamps, and is thus more easily available than hitherto. It was *a priori* probable that this gas of high atomic number would give much more favourable results than argon. The Gesellschaft für Lindes Eismaschinen, Germany, has kindly supplied me with compressed gas containing 94.5 per cent krypton and 5.5 per cent xenon. An ionization chamber was filled with the gas under a pressure of 12 atm. Only a few measurements could be carried out with the apparatus, as in consequence of an accident the greater part of the gas was lost. Nevertheless, the results obtained seem to be of interest to workers in that domain of science.

I had at my disposal two almost identical ionization chambers which were alternately filled with dry air under atmospheric pressure and with compressed krypton, argon or nitrogen. The chambers were of steel 5 mm. thick, had a volume of about 900 cm.³ each and their central electrodes were connected with Lindemann electrometers; they were exposed to the γ -rays from 0.4 mgm. radium at a distance of 120 cm.

Denoting by I_{air} the ionization in air of normal pressure and temperature, it was found:

$$I_{\text{N}_2}^{15.5 \text{ atm}}/I_{\text{air}} = 9.5; \quad I_{\text{Ar}}^{15 \text{ atm}}/I_{\text{air}} = 18.9; \\ I_{\text{Kr}}^{12 \text{ atm}}/I_{\text{air}} = 40.2.$$

The ionization at these relatively low pressures is roughly proportional to pressure². Reducing all measurements to the same pressure of 12 atm., we obtain the following relative ionization values for nitrogen, argon and krypton: 7.4; 15.1; 40.2. The nitrogen and argon used were of high purity; with commercial products, the superiority of krypton would be still more marked.

The γ -ray and cosmic ray ionization are generally proportional to each other. I undertook some experiments to test it in the case here concerned. My results are too incomplete to be quoted. It has been found, however, that the ionization due to cosmic rays is more than twice as great in krypton as in argon. It is thus obvious that the substitution of argon by krypton in ionization chambers will give a gain even more considerable than that which was

formerly obtained by substitution of air by argon. The usefulness of krypton for Geiger-Müller counters in cosmic ray research is also obvious.

Part of the expense for this investigation was covered by a grant from the Ministry of Education.

Ionization Energy of Li^+ and He

As a disagreement was found by Robinson¹ between measured and calculated values for the ionization potential of Li^+ , I have made a direct calculation by the method described by Hylleraas². The ionization potential in the 13th approximation is found to be 610,058 cm^{-1} . This result is in good agreement with the value 610,054 cm^{-1} obtained from the Hylleraas' extrapolation formula for $Z = 3$.

To this value the following corrections are to be applied³: ϵ_2 (mass polarisation correction—the elementary mass correction is contained in R_2 and therefore already taken into account), H_1 (relativistic change of mass with velocity), H_2 (magnetic interaction between the orbits), H_3 (spin correction, arising from a characteristic term in the Dirac theory), H_4 (relativistic correction for the remaining ion with one electron).

I have calculated the most important of these corrections, H_1 and H_4 , using the best wave function with four terms. Bethe has made the same calculation using a less accurate wave function.

TABLE 1 RELATIVISTIC CORRECTIONS.

Correction unit	H_1 $\alpha^2 R$	H_2 $\alpha^2 R$	H_3 $\alpha^2 R$	Total $\alpha^2 R$	Total (cm^{-1})
New value	153.8	-125.1	-20.3	+8.4	+49
Bethe's "	130.4	-111.6	-20.3	-1.5	-8

H_4 is found to be very little ($= -2 \text{ cm}^{-1}$). Other corrections seem to vanish in our approximation.

TABLE 2.

Unperturbed ioniz. pot. (cm^{-1})	Total cor- rections H (cm^{-1})	Mass pol. corr. ⁴ (cm^{-1})	Total calculated (cm^{-1})	Experimental value ⁵ (cm^{-1})
610,058	47	-5	610,100	610,079 $\pm$ 25

For He the agreement is not so good: the calculated value is 198,325 cm^{-1} (the unperturbed value is calculated by Hylleraas) and the experimental result is 198,305 $\pm$ 15 cm^{-1} (measured by Paschen). It seems that the theoretical values (even for heavier elements) lie somewhat higher than the experimental values, so the disagreement cannot depend upon the use of the variational method.

The O-H Raman Frequency in Inorganic Acids

THE band characteristic of the OH group has been recorded in the Raman spectra of many hydroxides and alcohols. It has not so far been observed, however, in the case of the stronger acids. Using the improved technique of complementary filters recently developed by Ananthakrishnan¹, and giving long exposures varying from six to twelve days, I have succeeded in obtaining spectra with sulphuric acid and crystals of iodic, selenious and telluric acids, in which the band is clearly seen in the 4046 Å. excitation. Table 1 gives the frequency shifts. The value for boric acid is taken from Ananthakrishnan's paper².

TABLE 1.

Substance	Raman frequencies of the OH band (cm^{-1})		
	Beginning	Middle	End
H_2SO_4 (100%) liquid	2794	2985	3172
HIO_3 crystals	2834	2979	3125
H_2SeO_4 "	2978	3067	3141
H_2TeO_4 "	2985	3121	3257
H_3BO_3 "	—	3172, 3256	—

The following points may be noted: (1) The OH frequency in these acids is represented by a band which is weak, broad and diffuse as compared with the other vibration frequencies. (2) The OH group, which gives a sharp line at 3608 in potassium hydroxide and a broad band at about 3660 in ethyl and methyl alcohols, gives a much lower frequency in the inorganic acids. (3) There is a progressive fall in the characteristic frequency shift and a diminished intensity of the band with increasing strength of the acid. (4) In the case of sulphuric acid, the band appears to be resolved into two components.

The fact that the OH band has not hitherto been recorded in the Raman spectra of acids has been regarded by some investigators³ as supporting the hypothesis of the existence of the so-called hydrogen bond⁴ in oxy-acids and their salts. Now that the OH band has actually been recorded, this view evidently requires some modification. We have in fact to postulate the existence of the OH bond in acids as well, but considerably weakened as compared with the strength of the bond in alkalis and in weak acids. It may be mentioned in this connexion that Badger and Bauer⁵ have recently observed an infrared absorption band in the region of 3μ in sulphuric acid, and they ascribe it to the presence of the OH group. These authors have drawn the inference that the so-called hydrogen bond and the hydroxyl bond postulated by Bernal and Megaw⁶ are only extreme cases of one and the same phenomenon. This view appears to be supported by the investigation reported above.

Surface Migration of Barium

J. A. BECKER¹ has described experiments from which he concluded that barium, deposited on one side of a flat tungsten ribbon, could, under given conditions, move to the opposite side. The thermionic emission measurements from each side of the ribbon indicated that barium deposited on one side migrated until each side was covered with half the original amount.

We have been engaged in observing the behaviour of oxide-coated emitters on nickel and tungsten, for which purpose we have used an electron microscope. In the light of Becker's results, we were surprised to find that, although barium could spread across a nickel or tungsten surface on which it had deposited, it could do so only when evaporation was possible. Our results did not, therefore, provide any direct evidence of surface migration.

We have since repeated Becker's experiments with both nickel and tungsten. The apparatus used by Becker is only briefly described in the references^{2,3} given, but in his paper⁴ on the diffusion and migration of thorium on tungsten, he describes in detail the apparatus employed. In our experiments, we used an apparatus similar to that described there. In this apparatus, precautions are taken to separate the thermionic emission from each side of the ribbon.

Our results have failed to reveal any evidence of surface migration of barium either on nickel or tungsten. In each case, the thermionic current measured at any time from the clean side was considerably less than one per cent of that obtained from the contaminated side, even after 16 hours' running at 1,100° K., the temperature at which Becker concludes migration rapidly takes place.

We hope to publish full details of both our electron microscopic and thermionic investigations in the near future.

The Ground State of the Se₂ Molecule

THE diatomic molecules of the lighter elements of the sixth family of the Periodic Table, like O₂, S₂, SO, have ³Σ terms as their ground states. There is some doubt if this still prevails with the heavier elements of that group. Spectroscopic investigations have so far not been able to show whether the ground states of Se₂, Te₂, SeO, etc., are ³Σ or ¹Σ states.

So it appeared worth while to ascertain the magnetic properties of Se₂ vapour. With all precautions necessary to avoid contamination by oxygen, selenium was sealed in a silica tube under vacuum, and the influence of a magnetic field on it was determined at different temperatures between 20° C. and 1,100° C. The vapour in the tube consists of Se₂ and Se₈, being practically all Se₂ at low temperatures and changing more and more to Se₈ as the temperature rises. Along with the formation of diatomic molecules, a strong paramagnetic influence appeared, rapidly increasing as the quantity of

diatomic vapour increased. This establishes the fact that the ground level of Se₂ is ³Σ.

A full account will be given in the *Proceedings of the Indian Academy of Sciences*, Bangalore.

Experiments on tellurium to the same effect are in progress.

A Psycho-geometrical Representation of Personnel Organization

LARGE industrial and other concerns represent their personnel organization diagrammatically by means of a chart having the form of a genealogical table. Properly constructed, this chart gives concise information as to individual rank and duties and relations, but no information regarding fundamental functions and mentality types at different levels. Moreover, the chart conveys the impression of descent instead of growth, differentiation and organic unity. It is therefore biologically unscientific and inadequate for administrative educational purposes.

Fig. 1.

The above defects can be remedied by employing the co-ordinate system. In Fig. 1 (of which a solid model in colours has also been constructed), the OX axis represents breadth of knowledge or the administrative function, and O-Y depth of knowledge or the research function. It will be apparent that the administrative mind is represented by a horizontal rectangle (A), the research or advisory mind by a vertical rectangle (R), and departmental management, supervision and labour by squares of decreasing size (D.M., S and L). A, R and D.M., though always different in form and function, may be equal in area or total knowledge and ability. These conceptions

constitute a helpful guide in educational training, including the important matter of mental contact. The projection (*OZ* axis) represents numbers only. It enables diagrams to be constructed representing the functional organization, in terms of mental types, of different concerns. Tentative trials have yielded interesting results. This method of representation, therefore, in psychological hands, has a research value.

It may be noted that *OX* also measures responsibility and power in the administrative sense. Remuneration increases from *O* to *X* in rapid geometrical progression ($r=2$); from *O* to *Y* it tends to increase only in slow arithmetical progression ($d=1$). This is due largely to demand and the factor of scarcity. It may be noted that knowledge and information characteristically pass along the path *YOX* and decisions or orders along *XOY*.

In Position II, the appearance of a building is not altogether fortuitous, since there is a fixed and real relationship between numbers and space, even if that between rank and altitude is only analogical. It may be noted that the modern idea of 'functional control' (for example, a personnel department 'intruding' into all other departments in respect of its function) can be represented clearly by lines drawn obliquely in the *XOZ* plane.

In the next two positions the figure facilitates the explanation of other ideas of considerable importance, but with which it is unnecessary to deal in the present communication.

Phosphorus and Calcium Deficiency Diseases as Two Aetiologicaly Distinct Entities

Phosphorus Deficiency

VITAMIN D deficiency in most species of animals leads to the development of rickets, and Kay's suggestion that the real cause of experimental rickets produced under conditions of vitamin D deficiency is the assimilation of insufficient dietary phosphorus is interesting. Certainly this opinion is strengthened by the observation that low vitamin D rickets is indistinguishable from that produced by phosphorus-deficient diets in the presence of abundant vitamin D. The disease is referred to as rickets in the immature animal and as osteomalacia in the adult.

Theiler produced evidence in 1932 that rickets or osteomalacia in bovines kept under conditions of abundant vitamin D was invariably associated with insufficient dietary phosphorus. Subsequent work at this Institute has shown this to be true for other species of domestic animals in addition to the ox. Experimental rickets, due only to insufficient phosphorus in a diet adequate in all other respects, has been produced in cattle, goats, sheep, pigs; and, recently, indications of it have been observed in the horse. Details of these experiments are being published and leave no doubt that insufficient dietary phosphorus is the causal factor in the production of rickets under conditions of vitamin D sufficiency, while insufficient calcium in the diet does not produce rachitic lesions but an entirely different bone disease.

Calcium Deficiency

It is well known that low calcium in the rations of horses, especially if excess phosphorus be present,

produces osteodystrophia fibrosa (Sturges and Crawford, Kintner and Holt, Niimi, Theiler, etc.) but not rickets. Actually, true rickets in the horse has not yet been described in the literature. Furthermore, osteodystrophia fibrosa (osteofibrosis) is known to occur also in the goat, the dog and in some other animals, but so far its occurrence has not been associated with calcium-low diets.

At this Institute an 8-months old calf receiving daily in the diet 3 gm. calcium (CaO) and an excessive quantity of phosphorus (30 gm. P_2O_5), developed marked osteofibrosis and bone atrophy after 13 months. Abundant vitamin D was present. Two calves of the same age and receiving the same ration except that the phosphorus content was reduced to 15 gm. P_2O_5 developed osteoporosis and severe osteofibrosis during the same period. A fifteen months old steer receiving daily in his ration 4 gm. CaO and insufficient phosphorus (4 gm. P_2O_5) developed rickets as a result of the phosphorus deficiency shortly after the beginning of the experiment and osteofibrosis in virtue of the calcium deficiency after 31 months, severe rickets and bone atrophy still being present. The same ration supplemented to contain abundant calcium (31 gm.) produced severe rickets and osteoporosis due to the phosphorus deficiency, but no osteofibrosis in a steer of the same age.

Moderate osteofibrosis was produced in a goat and in a pig receiving low calcium high phosphorus in their diets, but possibly the wide ratio of calcium to phosphorus was also responsible for the severity of the disease. Osteofibrosis has not yet been produced in sheep fed on a diet low in calcium.

Osteoporosis is merely the result of increased bone resorption; it is indicative of abnormal $\text{Ca}:\text{P}$ metabolism, and is a transient stage in the evolution of some osteodystrophic diseases. It invariably accompanies the development of both rickets and osteofibrosis.

The most probable explanation for the relative rapidity with which rickets was produced by phosphorus-deficient diets compared with the appreciably longer time osteofibrosis took to develop when the rations were low in calcium, is that the functions of these two minerals in the animal body differ widely. Practically all the body calcium is required for bone formation and is present in the skeleton, whereas the demands for the much more widely functioning phosphorus are far more varied than for calcium. In other words, the need for metabolic phosphorus, other than that required for ossification, probably plays as important a part in the production of rickets as a deficiency of phosphorus for bone formation alone, and hence rickets due to phosphorus deficiency appears more rapidly than osteofibrosis due to a deficiency of dietary calcium.

It is interesting to note that, in all Marek's experiments with pigs, osteofibrosis was produced only when calcium was low or lower than phosphorus. No significance was attached by Marek to this apparent association of osteofibrosis with reduced calcium in the diet, probably because the work was done under conditions of vitamin D deficiency, and hence rickets developed in every case where osteofibrosis was produced, thus masking the association of osteofibrosis with abnormal calcium metabolism.

Our conclusion is that when enough vitamin D is present, a deficiency of phosphorus in the diet of cattle, sheep, goats and pigs produces rickets only, whereas a deficiency of dietary calcium produces

osteofibrosis uncomplicated by rickets—certainly in cattle and horses and probably also in pigs and goats. Osteoporosis in invariably associated with both diseases.

Effects on Ovariectomized Rats of Progesterone Alone and in Combination with the other Sexual Hormones

An experiment on ovariectomized rats in relation to this question has been performed by Selye, Browne and Collip (1936)¹. They obtained progestational changes in the uterus and vagina of four out of six rats injected daily for 19 days with 30 γ of oestrone and 400 γ of progesterone.

We performed our experiments on 101 ovariectomized rats, which were injected with progesterone alone (up to 500 γ daily) or in various combinations with oestrone (the dose of oestrone varying from 1 γ three times a week to 30 γ daily) or oestradiol (30 γ daily or three times a week). The dose of progesterone used in these combinations varied from 500 γ to 3000 γ daily. Preliminary injections of 6 γ of oestrone were given four times a week for 10 days before the first progesterone injection was added. The period of injection was usually 20 days or, in a few experiments, 27 days.

The injection of progesterone alone (500 γ a day) brought about only a slight hypertrophy of the uterine epithelium and an occasional cystic mucification of some of the cells of the vaginal epithelium. The uterus and vagina remained atrophic, the average increase in weight being very small.

With the combined injections with oestrone or oestradiol, the nearest approach histologically to the picture of the normal pregnancy uterus and vagina was obtained by the use of 1 γ of oestrone three times a week with 1,500 γ of progesterone daily. Increasing the dose of oestrone, even to only 6 γ , or decreasing the dose of progesterone, resulted in a decrease or, with some doses, even in the disappearance of the progestational changes, especially those in the uterus. Even the combination of 30 γ of oestradiol three times a week with 3,000 γ of progesterone daily (that is, increasing both doses simultaneously) gave uterine progestational changes which were less than those obtained with the first combination 1 γ : 1,500 γ .

While, however, with some of the combinations mentioned above the histological structure of the uterus and vagina showed typical progestational changes, both the size and weight of these organs with all doses were considerably less than those during pregnancy (the sterile horn of a pregnant rat was used for the comparison of the uterine changes). In fact, the uterus was even much smaller than that of the normal rat in diestrus.

We have shown previously² that the so-called 'male' hormones, especially testosterone and testosterone propionate, when combined with oestrone, produce progestation-like changes in the sexual organs of ovariectomized rats, while at the same time these organs hypertrophy considerably. It is also known that the male sexual hormones (not identified) are present in the female organism. Taking these facts into consideration, various doses and combinations of testosterone, testosterone propionate and Δ^4 -androstenedione (150-500 γ daily) were added to the combination of progesterone and oestrone. A considerably improved general development was obtained in the uterus and vagina which, with some combinations of the hormones, approached that seen in pregnant animals. The myometrium considerably increased. The progestational changes in the mucosa, however, decreased somewhat after these additions.

The nearest approach to the 'pregnant' uterus and vagina was obtained in most of the rats injected with the following combinations and doses:

- (1) test. prop. 300 γ + prog. 2,000 γ + oestrone 6 γ ;
- or (2) test. prop. 500 γ + prog. 500 γ + oestrone 6 γ ;
- or (3) testosterone 500 γ + prog. 1,500 γ + oestrone 1 γ ;
- or (4) testosterone 500 γ + prog. 500 γ + androstenedione 500 γ + oestrone 6 γ .

We wish to express our gratitude to Prof. W. Schoeller and Messrs. Schering, Ltd., for kindly supplying us with progesterone, to Messrs. Ciba, Ltd., in particular to Dr. K. Miescher, for the supply of testosterone, testosterone propionate and androstenedione, and to Prof. A. Girard for oestrone and oestradiol.

Excretion of Nitrogen by Leguminous Plants

SINCE 1927, Virtanen and co-workers¹ have published results of numerous experiments which confirm and greatly extend the observation of Lipman² that certain leguminous plants when fixing nitrogen excrete part of this into the quartz sand substrate, and if a non-leguminous plant is present, it may utilize the excreted form. The extensive data compiled by Virtanen and collaborators prove definitely that true excretion occurs with several of the legumes, but there exists an equally impressive body of experimental data which demonstrates conclusively that excretion is not *universally* obtained.

The original experiments of Lipman included only twenty-six cultures free of combined nitrogen thus capable of supplying clear-cut evidence. With respect to excretion, six of these were positive and twenty were negative. Examination of Stalling's data³ shows no evidence of benefit to wheat when grown with soy beans. Ludwig and Allison⁴ report no excretion with cow-pea, lucerne, vetch and sweet pea, as does Bond⁵ with soy bean.

Since 1933 we have studied this problem using in most of our experiments a pea-oat mixture, but in certain ones lucerne, soy beans and red clover were included. In fifteen experiments, more than two hundred plant cultures grown under a wide range of

experimental conditions have been examined, but in no case has excretion been detected either by benefit to non-legume in association or through analysis of the sand.

At the invitation of Prof. Virtanen and with the aid of Dr. S. v. Hausen, I conducted experiments at the Biochemical Institute in Helsingfors during the fall of 1936. In spite of unfavourable weather, which restricted nitrogen fixation, definite evidence of excretion was obtained with peas grown in sterile containers. The experiments were repeated this spring at Madison under identical conditions with the exception of the sand used—and of necessity with different environmental conditions, for example, type of greenhouse and weather conditions. In these experiments, excretion has been detected in *part*, but not *all*, the cultures independent of the quantity of nitrogen fixed. The cause of the discrepancies is not readily apparent, but the chief factor in associated cultures appears to be the manner of development of the plants. Our experiments indicate that excretion may be profoundly affected both qualitatively and quantitatively by the species of plant, nature of substrate and in associated cultures by the relative rate of growth of the different species. An environment that delays the reproductive stage appears to favour the excretion process.

Without minimizing the importance of Prof. Virtanen's studies, especially as they relate to the chemical nature of the excreted compounds, it is emphasized that excretion of nitrogen by leguminous plants is not universally obtained, even under experimental conditions which are apparently identical. For this reason the questions as to whether the phenomenon actually occurs in the field and to what extent it is responsible for the beneficial effects of associated culture of legumes and non-legumes remain unanswered. Until the factors which control the process are defined and the origin of the discrepancies known, it should be recognized that application to practical agriculture is only an attractive possibility and not an established fact.

Succession of Broods of *Lebistes*

THERE seems to be a point in the natural history of *Lebistes* which is not generally known among those using this fish as a 'laboratory animal' in Great Britain. As it affects certain types of research very markedly, the following information will be of interest to those using this fish.

As a result of one mating, a female *Lebistes* may produce a succession of broods over a period of from six to eight months. From personal experience, I cannot vouch for the length of time mentioned (my authorities are Mellen and Lanier) as I am only now in the process of testing it, but that spermatozoa do remain alive within the body of the female and fertilize one brood after another is definitely established. The exact details of my data may be of interest. Mr. Gillespie sent me up some specimens

from the Zoological Society of Scotland's Aquarium on February 3 last. As a result of the rigours of the journey, all were dead by the morning of February 5 except two females. Hoping for the best, I got no more, and one of the two, which has had no other companion except the other original one since, has produced the following broods: February 22, 3; March 28, 20; April 25, 58; May 27, 28. Judging from her present appearance, she is again an expectant mother!

Method for Fixing Neutral-red in Supra-vital Stained Blood Smears

IN blood smears from horses stained according to the ordinary methods Giemsa and May-Grünwald Giemsa, we encounter serious difficulties in the examination: first, to differentiate between large lymphocytes and small monocytes, secondly, to determine *qualitative* changes in the white blood corpuscles. In order to remedy this, we have employed as a supplementary method, in an extensive investigation into the white blood picture in the case of infectious anæmia in horses, supra-vital staining with neutral-red.

We mix in a test-tube neutral-red with citrate blood at body temperature in the ratio of 1:15,000. The test-tube is placed in a thermostat at 37° for 40 minutes. In the meantime, it is shaken up a couple of times. After that we make an ordinary cover-glass smear, allow it to dry in the air for 24 hours, fix it with a saturated picric acid solution, and then stain it with Mayer's hamalin (that is, Mayer's original recipe without citric acid), and embed in cedar oil.

In this slide thus prepared from *normal* horses, there is a large granulated deposit of neutral-red in monocytes, eosinophiles and basophiles, while no neutral-red grains are discovered in neutrophils and lymphocytes. The difference between the neutral-red in lymphocytes and monocytes makes differentiation easy. In slides from horses suffering from infectious anæmia, there occurs during an attack of fever a more or less large deposit of neutral-red also in the neutrophils. It is often connected with degenerative changes. The degeneration is demonstrated by vacuoles in the protoplasm and karyopyknosis with strong lobation of the nucleus. We have been unable to discover in the sick horses any changes in the amount of neutral-red deposit in the other white corpuscles.

This method does not, of course, present any opportunity for the study of the live white corpuscles as does the method described by Simpson¹ and by Sabin², but in contradistinction to the latter it makes it possible to study the cells at leisure when fixation of neutral-red has been reached. The nuclear staining also largely facilitates the investigation. A great advantage is also the possibilities it presents in the study of qualitative changes in the neutrophile leucocytes.

Heterogeneous Equilibria with Deuterium

THE heterogeneous equilibria between hydrogen and the metallic chlorides have been extensively studied, notably by Berger and Crut¹ using a static

Fig. 1.

GRAPH I FOR HYDROGEN; GRAPH II FOR DEUTERIUM.

⊙, PARTINGTON AND TOWNDROW. (H₂)
○, " " " " (D₂)
⊗, JELLINEK AND ULOTH. (H₂)

method, and by Jellinek and his collaborators² using a dynamic method. More recently, Kapustinsky³ has studied the reduction of cuprous chloride with both

TABLE I

	H ₂ + CoCl ₂			D ₂ + CoCl ₂				
T°	673	723	773	673	698	723	748	773
10 ⁴ /T	1486	1383	1294	1486	1433	1383	1337	1294

	0.990 P. & T. 1.749 J. & U.							

hydrogen and deuterium, using a static method. The agreement among the results of different authors is not very satisfactory and we are engaged in further investigations of heterogeneous equilibria involving hydrogen and deuterium.

A static method has been used to study the reduction of cobalt chloride by hydrogen and deuterium. The cobalt chloride is heated with the gas at constant volume, the temperature being measured by a thermocouple, and pressure by a mercury manometer. The extent of the reaction is deduced from the increase of pressure due to the reactions:

The values of the equilibrium constant

$$K = \frac{C_{\text{HCl}}}{C_{\text{H}_2}}$$

obtained for hydrogen are in good agreement with those found by Jellinek and Uloth by a different method.

Table I shows the values of the equilibrium constant for hydrogen and deuterium at various temperatures. In Fig. 1 the logarithm of K is plotted against $1/T$, where T is the absolute temperature at which K is measured.

If K_1 , K_2 are the equilibrium constants for the reactions:

respectively, then $K^* = K_1/K_2$ is the equilibrium constant for the homogeneous reaction:

namely, $K^* = C_{\text{D}_2} \cdot C_{\text{HCl}}^2 / C_{\text{H}_2} \cdot C_{\text{DCl}}^2$

Urey and Rittenberg⁴ have calculated values of K^* at different temperatures on theoretical grounds. These are compared in Table II with values obtained experimentally by Kapustinsky and ourselves.

TABLE II

	1 + log K*				
T°	769	700	600	558	575
Urey and Rittenberg	0.96	0.94	—	—	0.91
Kapustinsky	—	—	0.78	0.70	—
Partington and Towndrow	0.92	0.89	—	—	—

The heats of reaction ($Q_p = \Delta U$) of reactions (1) and (2) above are deduced from graphs I and II to be $-31,850$ gm. cal./mol and $-30,790$ gm. cal./mol respectively, at a mean temperature of 450°C . The value given in the International Critical Tables for reaction (1) is $-32,860$ gm. cal./mol at 18°C . (determined thermochemically).

On plotting $\log K^*$ against $1/T$ a straight line is obtained from which the heat of reaction (3) is deduced to be $-1,100$ gm. cal./mol.

As would be expected from theoretical considerations, the value of K^* tends towards unity with increasing temperature, and the difference from unity may be shown to be negligibly small at 800°C .

The investigation is being extended to other types of reaction.

The Corona by Reflection from the Moon

THE light from the photosphere of the sun will illuminate not only the hemisphere of the moon facing the sun but also a zone five miles wide beyond the great circle bounding the hemisphere. A further zone five miles in width will be illuminated by those radiations emanating from the corona, if the height of the corona be regarded as equal to one radius of

the sun. The intenser light of the relatively low inner corona will fall on a narrow strip of this lunar zone, bordering upon the edge of the surface upon which the photospheric light is falling.

Let the slit of a spectrograph be placed across the illuminated portion of the moon's surface so that half the slit is projecting over the apparently unilluminated lunar surface. It will thus cross this five mile zone, which will be reflecting corona light. The spectrogram should reveal first a strip of the usual reflected sunlight; then, theoretically, the emission lines of the high chromosphere; and then the typical corona spectrum.

The practical difficulties involved are the very long exposure times which would be required to gather sufficient reflected corona light to give the image, and the very exacting requirements of guiding.

If one of the powerful long-focus telescopes were used for this investigation, and a 15-inch image of the moon were formed at the plane of the slit, then a five-mile strip of the moon's surface would be 0.95 mm. at the slit. Hence the need for very accurate guiding is obvious, so that the edge of photospheric illumination will not encroach upon this critical millimetre of the slit.

Since earthshine is strongest upon the moon during its early phase, this would not be a good time, but at and near half moon would seem to be the most favourable period.

In Fig. 1, AM is the radius of the sun; MN indicates the region of the corona; B is the moon; PEM is tangent to both moon and sun, and QFN is tangent to moon and corona. Thus EG bounds the photospherically illuminated portion of the moon, while EG and HF define the zone illuminated only by coronal light. Obviously this narrow strip of the moon's surface presents the largest target as viewed from the earth at first and third quarter.

Fig. 1.

The director of Mount Wilson Observatory has expressed his interest in this proposed method of investigating the corona, and suggests the desirability of having the method tried out at more than one observatory.

Viscosity of Binary Mixtures

THE equation¹

$$\log \eta = N_1 \log \eta_1 + N_2 \log \eta_2 \quad (1)$$

which is advanced by Dr. Lederer to give η , the viscosity of an ideal binary mixture, assumes that N_1 and N_2 are the physical molecular weights of the liquids 1 and 2 the viscosities of which are respectively η_1 and η_2 .

Now, if S_1 and S_2 are the association factors for the respective liquids, then the relation between m_1 and m_2 , the chemical molecular fractions of the liquids, and N_1 and N_2 is:

$$N_1 = \frac{m_1/S_1}{m_1/S_1 + m_2/S_2} = \frac{m_2 S_2}{m_1 S_2 + m_2 S_1} \quad (2)$$

$$= \frac{m_1}{m_1 + m_2 S_1/S_2}$$

If $S = S_1/S_2$, then

$$N_1 = \frac{m_1}{m_1 + m_2 S} \text{ and } N_2 = \frac{m_2 S}{m_1 + m_2 S} \quad (3)$$

S in equation (3) is, therefore, the ratio of the association factors of the liquids 1 and 2, respectively.

In Dr. Lederer's communication¹ the factor S is defined as the degree of association of component 2, but it would appear more correct to define S as the ratio of the association factors as derived in (3) above.

A further matter of interest is that the value of S varies (for the system benzyl benzoate in toluol at 25° C.—Kendall and Munroe's data) by 4 per cent about the mean value, as shown in the accompanying table.

m_1	$S = S_1/S_2$	
0.2357	0.803	
0.4331	0.818	
0.6503	0.840	Mean value 0.836
0.7890	0.862	
0.9002	0.860	

m_1 is the chemical molecular fraction of benzyl benzoate in toluol taken from Kendall and Munroe's data. Kendall and Munroe, however, showed that the freezing point data of solutions of benzyl benzoate in toluol were normal, whence $S_1 = \text{unity}$; hence the average value of $S_2 = 1.197$, that is, the average degree of association of toluol is 1.197 in this solution.

Dr. Lederer referred the value 1.197 to benzyl benzoate as an association factor, and in so doing appears to be in error.

It may be observed that an excellent test for the veracity of equation (1) above would be provided by an ideal binary mixture of components of approximately equal viscosity characteristic, because it is clear from relation (1) that if $\eta_1 = \eta_2$, then $\eta = \eta_1 = \eta_2$. Such a mixture should, of course, show no heat effects on mixing and have the

general characteristics which guided Kendall and Munroe in accepting benzyl benzoate in toluol as an ideal mixture. An approximate test obtains with the system propyl acetate + benzol—a system showing but a small heat effect on mixing—and, in this case, the value η is less than η_1 or η_2 , whence equation (1) cannot apply. Dr. Lederer's fundamental equation

$$\log \eta = m_1 \log \eta_1 + m_2 \log \eta_2 - \int \frac{qm}{4.57T^2} \quad (4)$$

however, provides for such cases where the integral involving the molecular heat of solution qm must be evaluated.

Use of the Word Substrate

IN recent years, the practice has grown up among workers in surface chemistry of using the word 'substrate' to denote the bulk phase underlying a surface film, regardless of the fact that this word has been in general use for a much longer time to denote the substance upon which an enzyme acts. The name as applied to a bulk phase on which a surface film rests would seem harmless enough in most cases, but since it is almost certain that, in enzyme action, the substance acted on is adsorbed, probably locally and one molecule thick, on the surface of the enzyme, the same word 'substrate' will have to do duty *both* for the underlying, and more

bulky, enzyme, *and* for the small molecules upon which the enzyme acts!

If the words 'substratum', or 'underlying liquid' (or solid, as the case may be) were used instead of substrate for the denser phase adjoining a surface film, I think this inconsistency, and possible source of confusion, in nomenclature, would be simply avoided.

Points from Foregoing Letters

THE isotopic and peaking fraction of krypton atoms of mass 78, 82, 84, 86, and of xenon atoms of mass 129, have been determined by Dr. F. W. Aston, by comparison with hydrocarbon 'doublets', by means of the mass spectrograph.

Dr. D. Crowfoot reports that the birefringent insulin crystals of prismatic type obtained by crystallization from acetate buffers at pH 5.2 gives similar X-ray patterns to those shown by the usual rhombohedral form, except for a more marked diffuse ring which may be due to the prevalence of amorphous matter, probably responsible for the prismatic form.

The probable absolute configuration of the naturally occurring α amino-acids has been demonstrated by R. C. Rainey by the application of Boys's rule to 2-amino-hexane, the configuration of which has recently been correlated with that of the amino-acids by Levene and Mardaahew; solvent action prevents the direct application of the rule to the 'amino-acids themselves.

Dr. St. Ziemecki, by replacing argon in a pressure ionization chamber for cosmic ray measurements by krypton, finds the effect was an increase of the ionization current, which was approximately 2.7 times greater than with argon at the same pressure. Thus by using krypton-filled chambers, it is possible to reduce greatly the pressure employed and hence the weight of the apparatus, which is of importance in measurements in high regions of the atmosphere.

By applying a number of corrections (due to mass-polarization, relativistic change of mass with velocity, magnetic interaction between the orbits, etc.) to the calculated value of the ionization potential of lithium atoms, H. A. S. Eriksson finds a value of 610,100 cm.⁻¹ in fair agreement with the experimental value. For helium, the agreement is not so good. Theoretical values are somewhat higher than experimental ones.

A band in the region of 3000 Å. of the Raman spectra of several inorganic acids observed by Dr. C. S. Venkateswaran is attributed by him to the presence of the OH group. The author gives a table showing the frequency limits of the bands in the cases of sulphuric, iodic, selenious, telluric and boric acids and, from their broad and diffuse nature, deduces that the OH group, though present in these acids, is much weaker in strength than the OH group present in the alkalis.

The surface migration of barium on to the opposite side of nickel and tungsten ribbon used in thermionic emission valves, as reported by J. A. Becker, is not

confirmed by Dr. M. Benjamin and R. O. Jenkins, even after sixteen hours running at 1,100° K.

Prof. S. S. Bhatnagar, Dr. H. Lessheim, and Mohan Lal Khanna find that the diatomic vapour of selenium is paramagnetic, which fact agrees with the view that the ground¹ level of Se₂ is ³Σ.

Experiments on animals are described by Dr. P. J. Du Toit and A. I. Malan to show that rickets result from a deficiency of phosphorus, even in the presence of vitamin D. Lack of calcium, on the other hand, leads to osteofibrosis.

Dr. V. Korenshevsky and K. Hall find that suitable combination of female and male sex hormones (progesterone, oestrone, testosterone and androstenedione) bring about normal pregnancy changes in the uterus and vagina of ovariectomized rats.

Prof. P. W. Wilson describes experiments made at Helsingfors, Finland, and others at Madison, U.S.A., in which both positive and negative results with respect to excretion of nitrogen by leguminous plants were obtained. He emphasizes that the existence of these negative findings together with the lack of clear definition of the conditions required for the occurrence of the phenomenon, make it impossible to decide at this time if the excretion plays a significant part in Nature.

The case of a female *Lebistes* (the 'millions' fish which devours mosquito larvae) which, as a result of a single mating has produced a succession of broods over a period of several months, is reported by G. L. Purser.

A method of staining smears with neutral-red, enabling one to differentiate between lymph-cells and small monocytes and to indicate qualitative changes in the white blood corpuscles (in infectious anaemia in horses) is described by A. Hjarre and H. Berthelsen.

The equilibria between cobalt chloride, and hydrogen and deuterium have been studied by Prof. J. R. Partington and R. P. Towndrow. Values of the equilibrium constant have been obtained at different temperatures, and from these the heats of reaction have been calculated.

ERRATUM.—Referring to his letter entitled "Collision of Two Oil Drops and the Stability of a Non-spherical Oil Drop", which appeared in NATURE of July 10, p. 70, Mr. Yoshio Ishida writes that owing to an error in the manuscript, 'oblate' should read 'prolate', and vice versa.

Research Items

Votive Offerings from Chichen Itza, Yucatan

ACCORDING to a recent announcement of the Carnegie Institution of Washington, D.C., some remarkable votive or possibly foundation offerings were found in the course of recent excavations at Chichen Itza, the famous city of the New Empire of the Maya of Yucatan, which flourished from the middle of the eleventh century of our era almost down to the coming of Columbus and the time of the Spanish conquest. The Carnegie Institution, which is working in co-operation with the Bureau of Pre-Hispanic Monuments of the Mexican Government, has been engaged in the exploration of El Castillo, the pyramid temple of the Maya god Kukulcan. This temple, built on top of a pyramidal structure, encloses completely, it has been found, an earlier temple and pyramid—a method of construction followed elsewhere in Yucatan. Excavation for the purpose of exploring the inner temple has led to some remarkable discoveries. In 1935, for example, a rectangular treasure box of limestone was found at the foot of a stairway. Its lid was a single stone, two and a half feet long by two feet wide. Among its contents were two turquoise mosaic plaques of great beauty, necklaces of coral, turquoise and jade, carved jade beads and pendants, and about 2,000 loose button-shaped beads of turquoise. The later find, made last season, was even more remarkable. In the inner chamber of the buried temple, of which the back wall was studded with the heads of human femora, presumably from sacrificial victims, there was found another box of squared limestone blocks, inside which was a throne fashioned from a single block of stone carved to represent a jaguar and painted a vivid red. The spots of the jaguar are represented by inlays of apple-green jade. The eyes are large hemispherical pieces of jade, the teeth and fangs of hard white stone. Its greatest length is two and three quarter feet, its greatest height to the top of the head, two and a quarter feet. Resting on the jaguar were a turquoise mosaic plaque, a shell necklace and a carved jade pendant. With much wisdom and judgment, the Mexican Government has decided that these finds shall remain *in situ* for the inspection of students and visitors.

Population Study of the Song Sparrow

MARGARET M. NICH has published a study, which extended over eight years, of a song sparrow population ("Studies in the Life History of the Song Sparrow 1. A Population Study of the Song Sparrow", *Trans. Linn. Soc. New York*, 4, April 1937. 1 dollar 50 cents). Each adult bird was marked individually with coloured bands. The various aspects of the life-history are clearly set out, from which a selection follows. The bird is a partial migrant at Cleveland, Ohio. About half the nesting males are resident, about half migrate. Of the females, only a tenth to a third are resident. A few individuals of both sexes changed status in different years. There was no evidence that the males with the larger territories, more vigorous song or brighter plumage, were more successful than their fellows in obtaining mates. There is not, apparently, a reservoir of unmated

birds of either sex to fill gaps due to mortality in the breeding season. The influence of warm waves of temperature on the commencement of song, migration and egg-laying is observed, and graphs show that the temperature-threshold at which each occurs is different at different times of year. Young often settled near their parents' territories, of which detailed genealogies are given, and one brother and sister mated. There is a detailed analysis of nesting success and survival of young and adults, and in a discussion of population limitation the importance of local changes in the environment is stressed. Territorial behaviour is considered to prevent overcrowding. There is also detailed information on weight, eggs, feeding times and other aspects of the breeding biology, and one chapter discusses the habits of the parasitic cow-bird. This is an important monograph, and the Linnean Society of New York has rendered a real service to ornithology by publishing it at such a moderate price.

Pituitary Extracts and Gastric Ulcers

A SERIES of papers by Prof. E. C. Dodds, working with various collaborators (*Proc. Roy. Soc., B*, 123, 22; 1937), gives a full account of some interesting observations on the effect of extracts of pituitary on the stomach. It has been found that extracts of the posterior pituitary containing the pressor principle produce gastric ulcers when injected in large doses into various animals. This observation provides a new way of studying methods of treating gastric ulcers. The production of ulcers appears to be due to the fact that the extracts inhibit gastric secretion, whether this secretion is due to histamine, insulin, sham feeding or pilocarpine. The action is primarily on the volume of the juice secreted. A continuous secretion of juice is probably necessary to protect the mucous membrane. A method is described for recording the gastric secretion and the blood flow simultaneously in an anesthetized cat's stomach. Stimuli causing secretion induce increased blood flow and if the increase in blood flow is prevented, secretion does not occur. The injection of pituitary extracts inhibits both blood flow and secretion. In normal animals blood flow and secretion are closely co-ordinated, but after hypophysectomy this co-ordination disappears. The possible significance of these results is widened by the observation that pituitary extracts have a similar action on pancreatic secretion. These facts are possibly related to the action of these extracts on the excretion of urine.

Early History of the Potato

DR. R. N. SALAMAN delivered the Masters Lectures of the Royal Horticultural Society last autumn, on "The Potato in its Early Home and its Introduction into Europe" (*J. Roy. Hort. Soc.*, 62, Parts 2, 3, 4 and 6; 1937). A mass of archaeological material has been marshalled to show that the potato was cultivated in South America at least so early as A.D. 200. Many representations of the tuber as a motif for the pottery of several epochs of South American history are illustrated, and show that the life of the Indian was closely linked with this plant.

Dr. Salaman also shows that the potato satisfied the conditions demanded by the physical setting of the Inca civilization, and provided a supply of food where the cereal grains failed. He agrees with Vavilov, Bukasov and other Russian investigators, that potato cultivation originated in two distinct areas—in the plateaux of Peru and Bolivia, and in Chile and the island of Chiloe. The Russians believe, on botanical grounds, that the southern focus of development supplied the ancestry of our present-day 'Irish' potato; but Dr. Salaman, using arguments provided by history, believes that the Peru-Bolivian source is much more likely. The potato entered Europe by two channels, namely, by way of England, and via Spain. Introduction into England, according to Dr. Salaman, cannot be readily dissociated from the names of Drake and Raleigh, in spite of the modern tendency to deprive these gentlemen of the honourable place in horticulture which tradition assigns to them. Dr. Salaman has ante-dated the first record of potato culture in Europe by fifteen years, with his proof that tubers were grown in the neighbourhood of Seville in 1572. He has also established the documented history of the crop for a very early period.

Fault-movements and the Safety of Reservoir Dams

In searching for reservoir sites among the coast ranges of California, engineers have found the most satisfactory features in certain fault-line valleys. The major faults of the district—the San Andreas, Hayward and Calaveras faults—have made possible the development of longitudinal valleys along parts of their courses, valleys so narrow that they can be closed by dams of moderate length. Dams have, indeed, been made across each of the three faults mentioned, and the question has been asked: Can a safe dam be built in a fault-line valley of a presumably active fault? Mr. G. D. Louderback has endeavoured to answer the question and to state the conditions that should be satisfied in their construction (*Bull. Seis. Soc. America*, 27, 1-27; 1937). He shows how the activity of a fault may be determined by mapping the epicentres of recurring small earthquakes, and the map given of the three faults with the centres of the earthquakes of the years 1932-35 clustered along a great part of the course of each, reveals that they are all definitely active faults. The experience of past earthquakes makes it clear that provision must be made for a horizontal displacement of 15-20 ft. and a vertical one of 5-10 ft. The dam should therefore be 60 ft. wide at the crest with slopes of about 2:1. To avoid fracture, outlet pipes should be laid parallel to the active fault. Lastly, the dam and all its subsidiary structures should be built so as to resist a strong shock and also the effects of slumping and landsliding.

A Coefficient of Humidity

Among the series of papers of the State Meteorological and Hydrological Institute of Sweden is one (No. 11) entitled "A Coefficient of Humidity of General Applicability", by Anders Angström, which sets out certain ideas that were first discussed at the 1936 meeting at Edinburgh of the Union for Geodesy and Geophysics. The author points out the desirability of having some function which will indicate the humidity or aridity of any climate in respect of the soil, that is, which will take into account both the rainfall and the evaporation. A function of this kind was used by Lang in 1920, who took simply

the ratio of the annual precipitation to the sum of the mean temperatures of the frost-free months divided by twelve, while Martonne in 1926 took the ratio of the annual precipitation to $10 + T$, where T is the annual mean temperature (in each of these two cases temperature is measured in centigrade). Angström suggests an alternative function, having the advantage over the two cited that it is a continuous function of temperature and can be used in the study of arctic climates. It is represented by the expression 1.07^t , where t is the mean temperature. He finds that this function is closely proportional to the mean duration of precipitation for a month in the latter is measured in hundreds of minutes, and that it is very nearly equal to the humidity function of Martonne for monthly mean temperatures between 0°C . and 20°C . A table is given which enables the new function to be read off quickly in terms of t , and two maps show its distribution in January and July over north-west Europe and adjacent polar regions, including Iceland, Greenland and Spitsbergen.

Monomolecular Films

THE study of the orientation of the molecules in monomolecular films has become of such importance that Messrs. E. Havinga and J. de Waal, of the van 't Hoff laboratory of the University of Utrecht, have worked out a technique for the production and investigation of such films by electron diffraction methods, and have published an account of it in the issue of March 15 of *Revue des Travaux chimiques des Pays-Bas*. The film in the case described was of barium stearate prepared on the clean surface of water and floated by lowering the water slowly on to a thin solid film of nitro-cellulose or of gold leaf placed below the surface of the water. The film of nitro-cellulose itself was prepared by placing a drop of a solution of nitro-cellulose in amyl acetate on a clean water surface. On evaporation of the solvent, a film of about 300 Å. thick was produced. An electron tube producing electrons of about 40 kilovolts path was used, and it was found that in addition to the diffraction pattern due to the support, in each case a hexagonal pattern of spots was produced which is attributed to the barium stearate film. Full details of the most suitable technique are given.

Two Visual Binary Orbits

DR. R. V. D. R. WOOLLEY and L. S. T. Symms have recently published a paper in which they discuss the orbits of OΣ 38 (γ, Andromedæ) and β 101 9 Argus (*Mon. Not. Roy. Astro. Soc.*, 97, 6; April 1937). Both stars have completed at least one revolution, so that the periods can be determined with considerable accuracy. Orbits have been already published, and those given by the authors have been obtained by applying differential corrections to previous orbits. A description of the method for applying these corrections is given in each case. The ephemeris for the first binary shows a very small separation near periastron, and micrometer measures here would be useless. It is suggested that an interferometer might be used in 1946-47 when the separation is $0''.02-0''.03$, as the star is bright. The period is 56 years (a year greater than the period found by Hursey), the eccentricity and inclination being 0.92 and 109.2° respectively. In the case of β 101, the eccentricity and inclination are also high, the values being 0.69 and 77.8° respectively. The period of this binary is 23.18 years.

Growth Factors

A DISCUSSION meeting on "Growth Factors" took place at the Royal Society on Thursday, June 24. The discussion revealed the emergence of a line of biochemical application which hitherto has been obscured by the diversity of its interest.

For a number of years, sporadic reports have been published by workers in the fermentation industries and bacteriology that the growth of yeast and bacteria depends not only on the provision in the diet of gross sources of energy and nitrogen, but also on illusive materials—'bios', 'accessory growth factors', akin to the 'vitamins', responsible for the notioning of special phases of animal metabolism even for the growth of animals. More recently, these tentative findings have been reinforced by workers in other specialized fields, for example, in anatomy and protozoology, and, by the use of modern biochemical technique and knowledge, it would now appear that the case established in the nutrition of animals is equally established in the nutrition of the most diverse varieties of cells; namely, that all cells from the lowliest bacterium to the cells of the highest animals are enabled to carry out the series of reactions between the sources of energy and nitrogen, which result in the production of energy and growth, only by the agency of other substances mostly of a nature akin to those already described in animal metabolism—vitamins. The only notable difference between the various forms of life is that these accessory substances are normally synthesized by some cells but not by others, and thus in the former case these substances need not be supplied in the nutrient diet.

The proceedings were opened by Prof. F. Kögl, of Utrecht, with a review of the present state of knowledge of the plant hormones, auxin- α and - β and steriauxin (β -indolylacetic acid). The auxins were at first thought to exert their effect on cell elongation, but now it is recognized that they regulate plant growth in many ways. Auxin- α , for example, is thought to account for the phenomenon of phototropism. Auxin- α lactone loses its activity under the action of ultra-violet light, and thus the shaded side, maintaining a greater concentration of activity, would elongate and produce the effect of phototropism. The action of heteroauxin seems to be primarily associated with the formation of roots on stem cuttings. This action is, however, not dependent on chemical structure, since a number of unrelated substances have a similar effect, recalling the non-specificity of oestrogenic compounds described by Dodds and co-workers.

Prof. Kögl also gave an account of his 'biotin', a sulphur-containing substance of great potency which may be the chief component of 'bios', originally described by Wildiers as a necessary growth factor for yeast. Biotin has also been shown to have an effect on the growth of higher plants.

Dr. P. Fildes (London) reviewed the subject as it appears to the medical bacteriologist, tracing the evolution of the vitamin concept for bacteria from Wort and Ingram's growth factor for *John's* willus (1912) to the present time, when vitamin B₁ has been proved to be essential for *Staphylococcus* and propionic acid bacteria, and nicotinic acid or coenzyme for *Staphylococcus* and the influenza

bacillus. He laid stress on the facility with which bacteria can adapt themselves to altered nutritional conditions, and ascribed the fact that parasitic bacteria specially require growth factors to a loss of synthetic function which has resulted from long association with an environment in which these factors are preformed. These dependent bacteria can readily be trained back to their 'original' state, in which they can synthesize the factors and so do not require to be supplied with them. In a series of different species of bacteria, each ultimately requiring coenzyme for growth, it was shown that the complexity of the nutrients from which coenzyme can be synthesized depends upon the synthetic power of the bacteria at the time of examination.

M. André Lwoff (Institut Pasteur, Paris) pointed out that certain bacteria and Protozoa cannot grow without a supply of haemin, because they are unable to synthesize it from iron compounds in the nutrients. The importance of haemin is ascribed to its function as a stage in the synthesis of cytochrome in Keilin's system. Its effect is to increase greatly the oxygen consumption of organisms starved of it.

M. and Mme. Lwoff have demonstrated that the long-known 'vitamin factor' of the influenza bacillus is none other than Harden and Young's coenzyme or Warburg's co-enzyme. Metabolic studies have shown that coenzyme acts as a co-dehydrogenase for various substrates and much increases the oxygen uptake of influenza bacilli and anaerobic glycolysis. Both haemin and coenzyme function as bacterial growth factors as components of the dehydrogenase-cytochrome system of Keilin and Warburg.

Mr. B. C. J. O. Knight (London) gave an account of the *Staphylococcus* and *Sporogenes* factors referred to by Dr. Fildes. He showed that the former consists of nicotinic acid, a constituent of coenzyme and of the two halves of the vitamin B₁ molecule—the pyrimidine and thiazole rings. The activity of each compound depends strictly on certain chemical configurations. The *Sporogenes* factor has not been finally determined, but there is evidence that it may have a much wider importance than merely the regulation of the metabolism of the obligate anaerobes.

Dr. G. M. Richardson (London) described uracil, a component of nucleic acid, as an essential factor in the anaerobic growth of *Staphylococcus*. Uracil is synthesized by the organism aerobically, and therefore under these conditions its effect on growth cannot be demonstrated. Anaerobically, however, the synthetic power of the organism is sufficiently depressed to make the demonstration possible. No metabolic function has hitherto been ascribed to uracil.

In the discussion which followed the more formal proceedings, there appeared to be complete agreement between the various speakers not only in detail but also in the wider implications of the discussion. Dr. E. R. Holiday (London) referred to the demonstration of nicotinic acid in Knight's crude *Staphylococcus* factor by means of absorption spectra. M. Lwoff recalled other factors which have been found by his colleagues in the Pasteur Institute, namely, the forms of sulphur necessary for the growth of certain fungi (Volkonsky) and the sterols found by Mlle. Caillaud to be necessary for flagellates.

A Method of Determining Stellar Rotation*

WHILE rotational speeds of stars can be estimated from photographs of stellar spectra, the actual deduction of these speeds and the demonstration that the star is rotating depend on rather abstruse mathematical calculation which, however, leads to a comparatively simple working routine. A knowledge of stellar rotational speeds, while obviously worth determining in any event, has several immediate applications, such as assessing the age of the stellar system, and is especially important in discussing the state of affairs in stellar atmospheres, a high rotational speed tending to offset gravity and promote ionization. If the rotational speed of a star is determinable, then the 'proper' spectrum of the star can be deduced; that is, the light emitted by any element of the star's surface, as distinct from the 'integrated' spectrum directly observed. Owing to the minuteness of a stellar image in a telescope, the light from the whole of the star's surface passes into the spectroscopic, and the rotational speed of a star cannot be measured as can that of the sun by observing the Doppler displacement of the Fraunhofer lines from one limb as compared with the other.

Prof. Carroll's method depends on the fact that the observed shape of a stellar absorption line (that is, the graph of intensity plotted against wavelength) has certain peculiarities if the star is rotating.

If a star be rotating, then different elements of area on the surface of the star are moving towards or away from the observer with velocities in the line of sight which depend on their position on the stellar surface and the rotational speed of the star. Thus, the spectra from the different elements do not simply superpose, as they would in a non-rotating star, but are displaced somewhat with respect to each other, thus resulting in a shallow broadened line. The final observed line shape therefore depends on two factors, namely, (a) the shape of the line emitted by any element of the star and (b) the rotational displacement. The first factor is quite unknown—previous methods of estimating stellar rotational speeds, however, depended on assuming this to be known—but the second factor can be detected by the new method.

The equations connecting the 'proper' shape $\mathfrak{I}(\xi)$ of a line and the observed shape $\Theta(\xi)$ are

$$\Theta(\xi) = \frac{1}{a} \int_{-1}^{+1} \mathfrak{I}(\xi + \beta t) g(t) dt$$

where a is a numerical factor and equal to $\int_{-1}^{+1} g(t) dt$,

and $g(t)$ is a function that depends on the way the brightness of the star varies over its disk, and β is the rotational speed of the star.

The solution of this equation is¹:

$$\mathfrak{I}(\xi) = \frac{1}{2\pi i} \int_0^\infty \frac{e^{-u\xi}}{G(u)} \int_0^\infty \Theta(x) e^{-ux} dx du,$$

where $G(u) = \frac{1}{a} \int_{-1}^{+1} e^{-ut} g(t) dt$;

but this is unusable as it stands as $\Theta(x)$ is to be integrated over a certain contour in the complex domain and $\Theta(x)$ is only known for real values of x . Analytical investigation shows a simple way out. We form the real part of the Fourier transform of $\Theta(\xi)$

$$\text{namely, } f(u) = \int_{-\infty}^{\infty} \Theta(\xi) \cos u\xi d\xi, \text{ which is easily}$$

done and plotted as a graph of $f(u)$ against u . It appears that, if the star be rotating, $f(u)$ must vanish (have zeros) at certain values of the product $u\beta$. Now we find, by plotting $f(u)$, the values of u for which $f(u)$ vanishes and hence by simple division the value of β .

It is, of course, possible for $f(u)$ to vanish for other reasons; the importance of the method lies in the fact that, if $f(u)$ has several zeros, they must give (or some of them), if the star is rotating, consistent values of β . A further test is that the values of f from different lines must be the same. Thus, if several zeros from several lines all yield substantially the same value for β , we can feel with some confidence that the observed line shapes are really produced by rotational broadening. As the theoretically calculated values of $u\beta$ for which $f(u)$ vanishes depend somewhat on the law of darkening involved in $g(t)$, it is theoretically possible to test this law as well. Having found β , a further simple computation (forming $\mathfrak{I}(\xi)$ from its transform) yields the 'proper' shape of the emitted line.

A similar method can be applied to the problem of stellar expansion.

In interpretation of this procedure, it was explained that any arbitrary function of the type considered might be represented by a 'spectrum' of harmonic constituents. (Fourier's integral theorem) the result obtained meaning that, if the observed line shape is due to rotation, certain of these harmonic constituents must necessarily be absent. Practical tests for this give the information (a) whether the star is rotating, (b) the speed of rotation, that is the equatorial velocity in the line of sight, and (c) thus enabling the 'proper' shape of the lines in the stellar spectrum to be found.

Unfortunately, the lines to be examined are, if the rotational speed be high enough to be readily determinable, wide, faint, shallow lines, and the technique of stellar photographic spectrophotometry is strained to the uttermost in providing sufficiently accurate measurements of line shape. Prof. F. J. M. Stratton of the Solar Physics Observatory, Cambridge, is collaborating with the Natural Philosophy Department of the University of Aberdeen in attempting to produce sufficiently good observations, and very promising results are now being obtained.

In the case of one star, namely, Algol, independent measurements of rotational speed are available, and the direct measurements give 26 km./sec. as the equatorial line of sight velocity for this star, compared to 26 ± 3 km./sec. determined by Prof. Carroll's method, using an exceptionally well determined profile of the line Mg^+ at 4481 Å. obtained by Struve at Yerkes Observatory.

* Summary of a lecture on "Rotating Stars" delivered before the Newcastle-upon-Tyne Astronomical Society at Armstrong College, on March 11, by Prof. J. A. Carroll.

Aluminium Manufacture in Great Britain

WITH the exception of silicon, aluminium is probably the most abundant metal in the world, forming nearly one eighth of the earth's crust. Owing to the ready manner with which it combines with oxygen, it is never found, as most other metals are, in the metallic state. In a paper in the 'Aluminium Section' of the March issue of the 'Trade and Engineering Supplement' of *The Times*, Mr. W. Murray Morrison gives an outline of the position which the aluminium industry now occupies in the British Isles.

In 1921, the Lochaber Power Co. was formed and developed a large water-power station. When completed, this scheme will be capable of developing 100,000 h.p. continuously, and will be by far the largest hydro-electric development in Great Britain. The British Aluminium Co. operates three reduction works, at Foyers, Kinlochleven and Lochaber. These are supplied with pure aluminium oxide from their works at Larnie in Ireland and Burntisland in Scotland. These works in turn are supplied with crude ore, bauxite, from the Company's own mines, vast deposits being owned by it in the south of France and in some British colonies. There is one other producer of the crude metal in Great Britain, namely, the Aluminium Corporation, the supplies of alumina for which are produced at Hebburn-on-Tyne and reduced to the metal at Dolgarrog, North Wales.

The final forms in which aluminium reaches the public cover a very wide field. The two forms in which it is best known are for cooking utensils and foil. The advantages of aluminium vessels for cooking are their lightness, cleanliness, hygienic qualities and

heat conductivity, together with their immunity from chipping, rusting and burning; these properties have made them very popular. Aluminium foil has almost entirely replaced other kinds of metal foil and is adopted for the wrapping of cigarettes and chocolates, the capping of milk bottles and tea-chest linings.

In connexion with motor-cars, aluminium pistons are now very commonly employed. Aluminium, which is only one third the weight of iron or copper, made possible the remarkable increase in the speed of transport which has taken place during the last fifty years. Motor-vehicle owners are keenly alive to the fact that it costs a given sum to convey a given weight a given distance in a given time. There is an additional advantage of using aluminium in road vehicles, as the increased lightness sometimes saves an appreciable part of the motor tax in Great Britain and allows the vehicle to run at a higher speed.

In air transport, where lightness is a paramount consideration, aluminium and its alloys play a very important part. Only one metal lighter than aluminium, namely, magnesium, is used as the major constituent in the manufacture of light alloys. The production of magnesium is closely allied to the aluminium industry. For these two metals and their alloys the aircraft industry depends for many of its components.

In electrical transmission, aluminium has been most useful. In Great Britain, the transmission lines of the National Grid alone employ more than 20,000 miles of steel-cored aluminium cable.

Association for the Study of Systematics in Relation to General Biology

AN opening meeting of the "Association for the Study of Systematics in Relation to General Biology" was held in the rooms of the Linnean Society (by kind permission of the president and council) on Friday, June 25. The chairman of the Association, Dr. Julian Huxley, presided over a gathering of seventy-four biologists.

In his introductory remarks, Dr. Huxley outlined the history of the Association. He said that the movement commenced with informal meetings in the autumn of 1936 between certain members of the staff of the Royal Botanic Gardens, Kew, and the John Innes Horticultural Institution at Merton. These led to the formation, on May 3, 1937, of a joint zoological and botanical "Committee on Systematics in Relation to General Biology". This committee eventually changed its title to the present form, and a council and seven committees were elected. The council at present consists of the following biologists: J. S. Huxley (*chairman* of the Association), H. W. Parker (*zoological secretary*), J. S. L. Gilmour (*botanical secretary*), W. T. Calman, G. S. Carter, M. B. Crane, C. D. Darlington, C. Diver, E. B. Ford, R. Ruggles Gates,

H. Godwin, J. W. Gregor, M. A. C. Hinton, J. R. Norman, J. Ramsbottom, O. W. Richards, N. D. Riley, E. J. Salisbury, Miss B. Schafer, T. A. Sprague, W. B. Turrill, B. P. Uvarov, E. B. Worthington, Sir W. Wright-Smith.

Dr. Huxley then explained the aims of the Association, which may be summarized under the following heads:

(1) To examine the theoretical and historical bases and the practical aims of taxonomy, and especially the relation of phylogeny to cytogenetic and taxonomic data.

(2) To examine the criteria employed in defining species and other systematic categories in different groups and the possibility of obtaining greater uniformity in their usage.

(3) To consider how far in the light of cytogenetic, ecological, physiological, embryological, and paleontological data, existing classification might require to be modified and new subsidiary terminology to be introduced. Further, to investigate the relation of any such subsidiary terminology to the International Rules of Nomenclature.

(4) To investigate the data and material already available, either taxonomic or bearing on taxonomy, with the view of correlating them with general biological principles and of establishing generalizations in comparative systematics.

(5) To press for the appointment of additional taxonomists and other biologists to the staffs of museums and other appropriate institutions.

(6) To arrange for research into the relative importance of the various factors, internal and external, operative in different groups in producing speciation and other evolutionary processes.

(7) To co-operate in the production or improvement of handbooks on British animals and plants and in the eventual publication of a British Fauna and Flora on uniform biological lines.

(8) To suggest useful lines of biological work to natural history societies and to amateurs and to assist in its co-ordination.

(9) To investigate the best methods of teaching systematics and field work in universities and schools.

(10) To stimulate discussion and to promote co-operation between workers in different branches of biology on problems of taxonomic interest.

The committees so far formed, together with the particular items of the aims of the Association with which they are concerned, are as follows:

(1) Taxonomic principles (items 1-3). Convener: Mr. J. S. L. Gilmour, Royal Botanic Gardens, Kew.

(2) Comparative systematics (item 4). Convener: Mr. J. R. Norman, British Museum (Natural History), Cromwell Road, S.W.7.

(3) Research (item 6). Convener: Dr. W. B. Turrill, Royal Botanic Gardens, Kew.

(4) Handbooks (item 7). Conveners: Captain C. Diver, 40 Pembroke Square, W.8; Mr. M. B. Crane, John Innes Horticultural Institution, Merton, S.W.19.

(5) Natural History Societies (item 8). Convener: Mr. H. W. Parker, British Museum (Natural History), Cromwell Road, S.W.7.

(6) Education (item 9). Convener: Miss B. Schafer, John Innes Horticultural Institution, Merton, S.W.19.

(7) Publications (other than handbooks). Convener: Dr. C. D. Darlington, John Innes Horticultural Institution, Merton, S.W.19.

At the close of the meeting, fifty-three biologists, in addition to the existing council and committees, gave in their names as members. Any other biologists wishing to join the Association should send their names and addresses to one of the secretaries, stating in which particular committee they are interested. For the present there is no subscription or formal method of election.

Annual Conference of the Museums Association

THE forty-eighth annual conference of the Museums Association was held in Newcastle-upon-Tyne in the week commencing July 5. The chief impression which one gained from the Conference was that museum officials are considering their problems in a new and more critical manner.

The keynote was set by Alderman Charles Squire in his presidential address. As chairman of the Leicester Museums Committee for the past twenty-seven years, he could speak with authority, and did not hesitate to criticize the general failure of municipal councils to make adequate provision for their museums. Museums and art galleries have a high place in the educational and social scheme, and are not yet getting the support which they deserve. Alderman Squire also referred to the valuable work that could be done by museums in assisting to preserve local records and the amenities of the countryside.

Another critical paper was one by Dr. W. E. Swinton (British Museum, Natural History), on "Natural History Museums and the Community". Too many small natural history museums might have as their motto "How best to kill a love of Nature", and Dr. Swinton strongly advocated the elimination of useless material and better display of the collections, so that these might inspire the visitor with a greater interest in plants, animals and rocks in their natural settings. The paper dealt with many other points of practical importance, especially the need for having as curator one who was not only a scientific worker, but also a man of action.

In the same general field there was also a valuable discussion on "Simplifying Habitat Groups", to which Mr. R. K. Perry (Liverpool), Mr. T. Russell Goddard (Newcastle), Mr. W. E. Mayes

(Leicester), and Mr. R. Wagstaffe (Stockport) contributed. It was pointed out that in a zoological exhibit it is most valuable to have an indication of the natural habitat of the birds or animals displayed, but that the elaborate group, to be found in the larger American museums, is far too expensive for the smaller English institutions. The proposals made were in the direction of suggesting habitat by branches of trees, by plants, or by other background material, and by the careful arrangement of the specimens in natural attitudes.

On the archaeological side, current museum methods were again criticized, the speaker being Mr. Ian Richmond, of Armstrong College. Mr. Richmond answered the question: "What does an archaeologist expect of a museum?" He suggested that the museum should contain a full series of local maps, especially those showing human distribution at different epochs; that one exhibit at least should display all the objects and clues that had been obtained from a single excavation; and that, wherever possible, comparative series of exhibits should be set up. He also appealed for a simple classified system of storage of all material not on exhibition.

Within the scientific field there were some important papers of a descriptive nature. Thus, Col. E. E. B. Mackintosh, director of the Science Museum, described the special exhibitions which have been developed at that Museum since 1911. It is interesting to learn that these very successful displays, which in recent years have covered such subjects as refrigeration, rubber, electro-deposition, noise and smoke abatement, electric illumination and television, take from six to twelve months to prepare, and that

the cost of the exhibitions has varied from less than £500 to more than £3,000 (the latter cost being borne by the industry concerned).

In his account of the Hancock Museum, Mr. T. Russell Goddard explained that this institution is financed entirely by the Natural History Society of Northumberland, Durham, and Newcastle-upon-Tyne. It was characteristic of the scientific life of the past century that so much public service had been performed by voluntary effort; but at the present time the finances of the Society are scarcely adequate to maintain the Museum in an effective manner.

Lastly, a valuable account was given by Dr. Kathleen B. Blackburn (Armstrong College) on modern methods of pollen analysis in relation to archaeological finds from peat. Mr. H. A. Hyde (National Museum of Wales, Cardiff) also dealt with this subject, and stressed its importance to the museum curator.

On the art side, Dr. John Rothenstein, director of the City Art Galleries, Sheffield, described the work which is being done in his Galleries to give school-children a greater perception and understanding of contemporary art (especially in the form of household objects), while Mr. Richard Bach, of the Metro-

politan Museum of Art, discussed the vigorous way in which art collections are brought to the people in New York by the Museum's "Neighbourhood Circulating Exhibitions".

In general discussions the problem of bad museums was considered more than once, and Mr. S. F. Markham (Hon. Empire Secretary, The Museums Association), after carefully defining such museums, advocated that steps should be taken to close them. Dr. C. Hay Murray, in a paper on "Museums as Department Stores", suggested that the curator should regard himself as a salesman, and study the methods of the shopkeeper. No less important, but of a more domestic nature, were papers by Mr. Laurence Vail Coleman, director of the American Association of Museums, on "The Philosophy of a Museums Association", and by Mr. S. D. Cleveland (Manchester) on "The Future of the Museums Association". Judging from the keen interest which the Conference aroused, that future will be an active and successful one.

The next Conference of the Association (of which the headquarters are at Chaucer House, London, W.C.1) will be held at Belfast in the first week of July 1938.

Flight in the Stratosphere

ALL countries which are interested in aviation have been considering the possibility of extending their activities to aircraft in the stratosphere. The greatest advantage in flying very high is that much higher speeds can be obtained for the same expenditure of power as the density of air is so much lower in the stratosphere than at ground-level. The Schneider trophy was won, for example, at a speed of 430 m.p.h. with an engine which gave 2,200 h.p. In the stratosphere, a speed of about 800 m.p.h. could be obtained for the same power. To drive the Schneider trophy winner at the latter speed near the ground would require an engine of 30,000 h.p. If stratosphere flight were possible at 600 m.p.h., then New York would be only five hours from London; so that by local time a passenger from London would arrive at New York before he started.

In vol. 7 of the Cambridge University Engineers' Association Year book recently published, Captain J. L. Pritchard points out some of the difficulties involved in flying in the stratosphere, and concludes that these will probably prevent stratosphere flight becoming a regular service, at least in the present generation. In fact, the increasing engine temperatures due to the difficulty of getting greater cooling may make regular flights in the stratosphere impossible until a new source of power is discovered.

The output of the internal combustion engine can only be maintained if the weight of oxygen it takes in per minute is maintained constant. At an altitude of 60,000 feet, the density of air is only about a tenth of what it is at ground-level. To maintain its output the engine would have to run ten times faster than at ground-level or take in ten times the volume of air.

The former alternative is impracticable so the weight of the air would have to be kept constant by supercharging. During this process, the pressure of the air is raised to about that at ground-level and the temperature by about 300° F. As most of the heat given in the air supplied has to be dissipated, extra cooling is necessary. Despite its low temperature, the low pressure of the atmosphere at this height is a disadvantage. Supercharging requires greater weight of equipment; in fact, the higher the aeroplane the greater its requisite weight.

In 1931, Prof. Picard discovered another fact which increases the difficulties of arranging for cooling. He found that at a height of ten miles, the temperature outside his gondola was -87° F., whilst inside the temperature was 140° F. This was due to the radiant heat absorbed by the gondola. As a method of getting over these difficulties the rocket principle has been suggested. This doubtless would work better at low temperatures than at the ones at which it has been tried. It has to be remembered also that the velocity of sound in the stratosphere is about 700 m.p.h., a speed which enthusiasts think aircraft might attain. Some engineers think that the aeroplane will have a critical speed at this speed, but it is not known how it would get through this critical speed. For this speed, the aeroplane would probably require small wings and the landing speed might have to be about 130 m.p.h.

As an offset to these disadvantages, there would be a great saving of fuel for the journey and the time would be much shorter. In the event also of an emergency landing, there would be a much greater choice of landing grounds, as it would be possible to travel 140 miles with the engine cut off by gliding from a high altitude.

University Events

BELFAST.—In connexion with the annual meeting of the British Medical Association recently held in Belfast, the following honorary degrees have been conferred: *doctor of laws*: Dr. G. C. Anderson, medical secretary of the British Medical Association; Sir E. Farquhar Buzzard, professor of medicine in the University of Oxford, physician to His Majesty the King, and president of the British Medical Association; Dr. H. Morley Fletcher, consulting physician at St. Bartholomew's Hospital and former president of the Association of Physicians; Prof. E. W. H. Groves, emeritus professor of surgery of the University of Bristol: *doctor of science*: Prof. S. P. Bedson, professor of bacteriology in the University of London; Dr. A. Felix, of the Lister Institute, known for his researches on typhus and enteric fevers.

CAMBRIDGE.—The Frank Smart studentship in botany will be vacant on October 1, 1937. Any graduate of the University is eligible for the studentship, which is valued at £210 a year. Further information can be obtained from Prof. F. T. Brooks, at the Botany School.

The Benn W. Levy research studentship in biochemistry will become vacant on October 1. Applications for its tenure should be addressed to Sir F. Gowland Hopkins at the School of Biochemistry before July 24.

LEAMING.—The Clive Behrens lectureship has been instituted by means of an endowment of £1,000 given by the Hon. Mrs. Behrens. The lecturer will be appointed biennially to give a series of four, five or six lectures on a subject germane, and of importance, to the practice of agriculture.

LONDON.—Mr. A. A. Miles has been appointed, as from October 1, to the University chair of bacteriology tenable at the University College Hospital Medical School. Since 1924 he has been University reader in bacteriology at the British Postgraduate Medical School.

Prof. J. H. Dible has been appointed, as from October 1, to the University chair of pathology tenable at the British Postgraduate Medical School. Since 1929 he has held the George Holt chair of pathology in the University of Liverpool.

OXFORD.—E. H. Leach, Oriel College, has been appointed to the new lectureship in physiology on the foundation of William Hulme at Brasenose College.

M. S. Wills, University College, has been awarded the Scott scholarship in physics for two years from October 1.

F. G. W. Knowles, Oriel College, has been elected to the Naples biological scholarship for the year 1937–8.

F. Fulton, Pembroke College, has been awarded the Radcliffe scholarship in pharmacology.

A special number of the *University Gazette* has been issued containing notices of the scholarships and exhibitions announced for the year 1937–8 by the men's colleges. In all, there are about 210 scholarships and 105 exhibitions open for competition. Of these, 37 and 16 are to be awarded for natural science, 13 and 6 for mathematics, 6 and 2 for either natural science or mathematics, and 8 and 5 for any of five subjects of which natural science and mathematics are two.

Science News a Century Ago

A Fatal Parachute Descent

IN Airy's "Autobiography" in the notes on the events of 1837 is one stating, "On July 24th I saw the descent of the parachute by which Mr. Cocking was killed. I attended the coroner's inquest and gave evidence a few days later". Robert Cocking was landscape painter, who in his earlier days had been a member of the City Philosophical Society with which Faraday was connected. In August 1814, he had lectured to the Society on aeronautics and had received a medal from the Society of Arts. In 1833 he made a curious form of parachute like an inverted truncated cone, 34 ft. in diameter at the top, which was formed of a circular metal tube 2 in. in diameter. A wooden hoop 3–4 ft. in diameter formed the lower edge, and between the hoop and tube was stretched strong linen. It weighed about 150 lb. Being most anxious to try it, he prevailed upon Green, an aeronaut, to ascend in a balloon from the Vauxhall Gardens on the evening of July 24, with Cocking, and his parachute suspended beneath the balloon. Having travelled as far as Lee, Cocking released himself, the parachute collapsed and he was killed.

The inquest was held at the Tiger's Head, Lee and attracted a great deal of notice. Airy had watched the balloon through a telescope, and he and other scientific men gave evidence at the inquest. Green, in his evidence, said that he had an unconquerable objection to parachutes which he considered quite useless and not likely to lead to any good end. In the course of the inquest, Faraday's name was mentioned as having spoken with Cocking at the Gardens before the ascent, and on July 31, Faraday wrote a letter to *The Times* in which he referred to the lecture of Cocking, and his recollection of the inventor's "companionship, abilities and kindliness". The verdict at the inquest was that, "We find that the deceased Robert Cocking, came to his death casually and by misfortune, in consequence of severe injuries received by a fall out of a parachute of his own invention and contrivance, which had been appended to a balloon; and we further find that the parachute did move to his death, and therefore that such parachute ought to become a deodand and forfeited to the Queen". Cocking, who was sixty-one years of age, was buried in a grave next to that of Halley and Pond at Lee.

Telegraphic Communication on Railways

WHEN Wheatstone and Cooke patented their electric telegraph, Robert Stephenson and the directors of the London and Birmingham Railway sanctioned the laying of wires between the Euston Square and Camden Town stations. Towards the end of July 1837, the telegraph was ready and Dr Andrew Wynter in his "Curiosities of Civilisation" said: "Late in the evening of the 25th of that month, in a dingy little room near the booking-office at Euston Square, by the light of a flaring dip-candle which only illuminated the surrounding darkness sat the inventor, with a beating pulse, and a heart full of hope. In an equally small room at the Camden Town station, where the wires terminated, sat Mr Cooke, his co-patentee, and among others, two witnesses well known to fame—Mr. Charles Fox and Mr. Stephenson. . . . Mr. Cooke in his turn touched the keys and returned the answer. 'Never did I feel

such a tumultuous sensation before,' said the Professor, 'as when all alone in the still room I heard the needles click; and as I spelled the words, I felt all the magnitude of the invention, now proved to be practical beyond cavil or dispute.' The telegraph thenceforward, as far as its mechanism was concerned, went on without a check, and the modifications of the instrument, which is still in use, have been made for the purpose of rendering it more economical in its construction and working, two wires at present being employed, and in some cases only one."

Artificial Digestion

THE *British and Foreign Medical Review* of July 1837 contains the following information: "Dr. T. J. Todd of Brighton with the assistance of Mr. Schweitzer of the German Spa, Brighton, has been performing experiments with the artificial digestive fluid, in imitation of those of Schwann in Berlin and has arrived at some new and interesting results not attained by Dr. Schwann. The digestive fluids with which Dr. Todd operated were prepared from the stomachs of the ox, the horse, the dog and the cat. Some, also, prepared from the upper portion of the small intestines, was found not less powerful. The presence of the acid is essentially necessary in the preparation; when Mr. Schweitzer endeavoured to procure the digestive fluid with distilled water alone, or when he treated the mucous membrane in the same way with a weak alkaline solution, a rapid putridity stopped all further proceedings. Various animal and vegetable substances were submitted to the action of these digestive fluids, at the ordinary temperature of the atmosphere, and the contact result in all the instances had been that these substances have been resolved into their elementary organic globules."

"There has been no exception to this, so far as the experiments have extended, and these include among vegetable substances the artificial digestion of boiled cauliflower, of bread, and of vermicelli, not dressed; and among animal substances, the white of egg boiled, the coagulation of blood, butter, fat, the muscular fibre of mutton and of fish boiled and raw, filaments of the sciatic nerves raw, and scrapings of bone. The products of these artificial digestions especially of the vegetable substances compared with chyme taken from a dog which had been feeding upon ground oats, were very much alike, except that the watery part had been removed from the chyme."

Cure for Drunkenness

THE issue of the *Indian Journal of Medical and Physical Sciences* of July 1837 contains the following information: "A native of Norway, aged 40, who had from his youth been accustomed to dram drinking, was attacked with delirium tremens. His medical attendant to cure him of his dangerous propensity, prescribed the daily dose of a mixture of two drachms of sulphuric acid and twenty-four ounces of whisky. The result was remarkable. In three months' time he got such a dislike to all kinds of spirituous liquors that he could not bear to swallow a drop of anything stronger than beer. The dose of the above mixture taken, was four wine-glasses daily, and the cure had been of a year's standing at the time of the communication of the case."

Societies and Academies

Dublin

Royal Irish Academy, May 10.

W. J. McCALLIEN: Structure of the Rathmullen District, Co. Donegal. An account is given of the Crana quartzite in the district between Rathmullen and Milford. It can be split into three divisions. The structure of the quartzite group is described, and emphasis is laid on the value of the epidiorite sills in the interpretation of the structure. The base of the quartzite is believed to be a slide, which is folded and overfolded. The Killygarvan limestone, which is younger than the Crana quartzite, is correlated with the Culdaff limestone.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the day mentioned:

PROFESSOR OF CIVIL ENGINEERING, IRRIGATION AND HYDRAULIC in the Thomson Civil Engineering College, Roorkee, United Provinces India—High Commissioner for India, General Department, Indi House, Aldwych, London, W.C.2 (July 31).

HEAD OF THE DEPARTMENT OF ENGINEERING, ARCHITECTURE AND BUILDING of the Bradford Technical College—The Principal (July 31)

ASSISTANT ENGINEER in the Mechanical and Vehicle Engineering Section at the Headquarters of the Ministry of Transport—The Establishment Officer (July 31).

ASSISTANT CURATOR in the Rock Garden and Herbaceous Department of the Royal Botanic Gardens, Kew—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W. (August 2).

PERMANENT ASSISTANT (metallurgy) in the Admiralty Technics Pool—The Secretary of the Admiralty (O.R. Branch) (August 7).

PROFESSOR OF FORESTRY in the University of Aberdeen—The Secretary (November 1).

ASSISTANT LECTURER IN CIVIL ENGINEERING in the Imperial College of Science and Technology (City and Guilds College)—The Secretary.

TEACHER OF ENGINEERING in the Oldham Municipal Technics College—The Director of Education, Education Office, Oldham.

LECTURER IN MATHEMATICS and LECTURER IN CHEMISTRY in the Kingston Technical College—The Principal.

LECTURER IN ENGINEERING in the Brighton Technical College—The Education Officer, Education Office, 64 Old Steine, Brighton, 1

ABSTRACTOR of scientific and technical literature at the Shire Institute, Didsbury, Manchester—The Director of Research.

Freedom of Science and Learning

SO much has been said recently upon the subjects of academic freedom and intellectual liberty that there is a tendency for the terms to become catchwords, as in the much-used phrase "Poverty in the midst of plenty". If this were the main result of the reiteration of the principle that scientific inquiry can only develop to its full extent in an atmosphere of political freedom, it might reasonably be suggested that there has been too much talk about liberty but too little done to secure it. Fifty years ago, as Prof. Hogben reminded us in his Conway Memorial Lecture—"The Retreat from Reason"—T. H. Huxley, in an address on technical education, used the pregnant words "The great end of life is not knowledge but action"; and this principle may be applied very appropriately to the reaction that has resulted from a knowledge of conditions deliberately created to restrict scientific work to particular classes, and thus to destroy the international character of the pursuit of scientific truth.

The group of British scholars and scientific workers who, under the leadership of Lord Rutherford, formed the Academic Assistance Council in 1933 wished to defend the principles of university freedom by actions rather than words. As the Council's report*, which has recently been published, says, the Council has relied on the propaganda of practical achievement; not of protest or agitation. The achievement disclosed by the report is remarkable. Of the approximately 800 refugee University teachers from Germany, 485 are permanently re-established and 320 have been provided with temporary positions enabling them

to continue their scientific work. This work has been accomplished during a period of economic depression, which has weakened the absorptive capacities of the universities and increased national protectionist activities in the learned professions of all countries. The report emphasizes that the Council itself is directly responsible for only a part of this achievement; the Council is the institutional expression of a spontaneous activity in the university world to assist the displaced scholars. It is, therefore, the index of a great co-operative achievement by the free universities, the success of which, in contrast to the relatively unsatisfactory progress made towards a solution of the refugee problem in general, proves that it depends chiefly not on motives of compassion but on convictions that the principle of university freedom is involved, and is implicitly defended by assistance for the refugee scholars.

The report is a demonstration of how vigorous is the determination to defend liberty. The work in itself has strengthened that liberty. University teachers, co-operating in the work of academic assistance which the Council has kept consistently on a basis of political neutrality, and associating with the exiles who have suffered by the destruction of liberty, must have learned during the past four years to value more highly the practical advantages of their own freedom. Furthermore, the proof that in a crisis men of science can rely upon the moral and effective support of their colleagues in other countries must have increased that security which is a condition of freedom. It cannot be hoped that the leaders of intolerance and irrationalism will be deterred by the knowledge that their victims will be sheltered in the asylum of liberal countries; but we may hope that

* Third Report of the Academic Assistance Council (Society for the Protection of Science and Learning, 6 Gordon Square, London, W.C.1). Copies may be obtained gratis on application to the General Secretary of the Society.

their opponents will feel slightly more secure in their opposition, and we shall be spared a repetition of what still remains the most tragic feature of the German disaster, the absence of any stubborn resistance by the universities themselves to the restriction of their freedom.

The report makes it clear that university teachers in several countries will need all possible moral encouragement in face of the widening menace to the security of learning. Realizing this, the Academic Assistance Council has converted itself into a more permanent organization, the Society for the Protection of Science and Learning. The dismissal of university teachers in Germany on 'racial' grounds has seen two main phases—that after the original legislation of 1933 and that after the Nuremberg legislation in the autumn of 1935. Information in the last few weeks suggests that a third phase is beginning; for a considerable number of professors have recently been dismissed merely because they have Jewish wives. Parallel with the series of dismissals on 'racial' grounds there has been a continuing process of dismissals on grounds of 'political unreliability'. The law of January 21, 1935, providing for a 'fundamental reconstruction of the universities' has been used for arbitrary dismissals when the other regulations did not provide so convenient a pretext. The report gives details of the displacement of scholars in other countries on grounds of religious or political opinion; for example, in Italy, Portugal and the U.S.S.R., and of the beginnings of a refugee movement from Spain in consequence of the civil war. The Society considers that its services are even more necessary to-day than when the Academic Assistance Council was founded in May 1933.

It may be asked why Great Britain should take a leading part in this work of salvaging scholarship wrecked by the subjection of universities within the new authoritarian States, and whether the work is worth while. On grounds of principle, there can be little doubt that our tradition of toleration imposes on us a special responsibility, and that it is justifiable in defending principles to protect those who have been victimized by the non-recognition of those principles. Doubts arise, however, not on theoretical grounds but on practical considerations. The Society's report describes fully its methods of work and convincingly answers the possible criticism that the sheltering of the refugees in Great Britain has injured the interests of British university teachers by pointing out that its work

has "protected them from the injury that was threatened in the situation in 1933 when an army of wandering scholars invaded the university world, without guidance or directed distribution and when no new financial resources were available with which the universities could meet the crisis". It is pointed out that, for the future, the efficiency of the work in re-establishing the scholars will make it necessary for almost all to be assisted to re-establishment in over-seas countries without even a period of sojourn here. We must keep a sense of proportion in this matter. There are 228 German *émigré* scholars in Great Britain, and it cannot be seriously claimed that they threaten the professional interests of the 6,000 British university teachers. During the past four years the Council alone has added a sum of £35,000 to the resources of the universities, which has enabled them to bear the additional strain so unexpectedly imposed.

Hospitality is a two-way process, and it is evident how greatly the universities have profited from their guests. One of the German men of science who had found asylum in the United States was urgently invited by Herr Rust to return to Germany, where his ancestry would be forgiven because his services were required in the rearmament programme. He declined the invitation, expressing the hope that Herr Rust would succeed within ten years in benefiting the German universities as much as he had benefited the American universities within one year. It is rumoured that a certain institution not far from Cambridge has considered the advisability of erecting a tablet in gratitude for the benefactions bestowed on it by the results of the new National Socialist régime. The pages of NATURE itself almost each week show how much of the learning and talent that was threatened with extinction in Germany in 1933 has been preserved through the agency of bodies like this Society.

In the gloomy pages of the history of the German universities in the last four years, the work of the Society for the Protection of Science and Learning stands out in happy relief. The Council asks for continued support for its activities and hopes that many will associate themselves with the work by becoming members of the Society. Few subscriptions to societies can show such good profit as a guinea membership subscription to this Society, which is trying to protect science and learning.

Messianic Radiation

Star-Begotten :

a Biological Fantasia. By H. G. Wells. Pp. vii+199. (London: Chatto and Windus, 1937.) 3s. net.

IT is always interesting to see what a scientific fact will look like after Mr. Wells's imagination has been let loose on it. The facts on which this book is based are that particles or photons of high energy provoke mutation, and that such particles and possibly photons are reaching our planet from outside. What if some intelligent extra-terrestrial beings, perhaps on Mars, are treating us as we treat *Drosophila*? If these beings are as benevolent as they are powerful, may we not expect that our mutations will be of a desirable character, and that the mutants will reform the world? So Mr. Wells's characters argue. Two thousand years ago Virgil was writing:

"Iam nova progenies coelo demittitur alto"; and it is widely believed that his prophecy was fulfilled. Wells predicts not a single saviour, but millions of messianic mutations.

It is worth while pointing out why such a theory, even if there were some evidence for it, would be unacceptable. First, as Wells himself remarks, the cosmic radiation is undirected. As a theme for his next story, I offer him the radiation of about 15 metres wave-length which Jansky found to be reaching our planet from the hub of the universe, or rather of our galaxy, in Sagittarius. Secondly, spontaneous mutation has a fairly high temperature coefficient, and therefore cannot well be due to radiation. Muller discovered this fact before he showed that X-rays are more effective than heat in provoking mutation. But radiations are new, and temperature coefficients are not, so the discovery is generally ignored. Finally, cosmic radiation obeys (if one may use such a word) the uncertainty principle, so even a superhuman marksman aiming at particular genes in human nuclei could scarcely expect much success. It is interesting that temperature fluctuations are equally uncontrollable, so that at present we have no method which promises anything better than a random provocation of mutations, most of which are harmful.

Why, we may ask, has our author chosen this particular theme? Many of my younger contemporaries, in Flecker's words,

"Take no more solace from the palm-girt Wells".

I think they are wrong. He still represents an

important tradition, he is a great stylist, and the workings of his mind are most instructive. "Star-begotten", like Stapledon's "Last and First Men" and "Odd John", but unlike his recent "Star-Maker", despairs of existing humanity, and demands beings of innate endowments superior to our own to deal with the present crisis of civilization, which it sketches in brilliant phrases. The author is obviously sceptical of the remedies which he and others have propounded. "Haven't all civilised men nowadays the feeling of being dillettantes on a sinking ship?" asks one of his characters. So with unconquered optimism he puts forward a panacea which he knows to be fantastic.

Some of the undercurrents of Wells's thought are indicative. He is strongly anti-communistic, but he cannot help being influenced by communist ideas. Thus he uses the word ideology, and on p. 165 we find a phrase about mad dogs which perhaps owes something to a speech of Vishinsky's at the first trial of Trotskyists in Moscow. Many of his phrases remain apposite if the letter 'x' is substituted for 't' in Martian. Making this substitution, we read "At the onset of a strange way of living we bristle like dogs at the sight of a strange animal. He hated these Marxians as soon as he thought of them. He could not imagine that their interference with our nice world could be anything but devastating". Another character is more tolerant. "And now these new creatures from outside, these creatures called Marxians, are coming on board our drifting system. With their hard clear minds, and their penetrating unrelenting questions stinging our darknesses as the stars sting the sky. Are they going to salvage us? Shall we let them if they can?"

Whether or not the Marxians have correctly diagnosed the cause of our present distresses, it is clear that evolutionary processes, either natural, or directed by terrestrial or celestial eugenicists, are most unlikely to end them. The time-scale of evolution is altogether longer than that of history; and we probably have not many years, let alone generations, to save our civilization from collapse. If this book encourages a single reader to think, even for one moment, that any natural or super-natural process will take the place of human effort and human thought, then it is a bad book. But if it is read as a record of conversations between rather worried intellectuals, it is not only an excellent piece of writing, but also a valuable historical document.

J. B. S. H.

The Dilemma of Contemporary Linguistics

Infant Speech: a Study of the Beginnings of Language

By M. M. Lewis. (International Library of Psychology, Philosophy and Scientific Method.) Pp. xii+335. (London: Kegan Paul and Co., Ltd., 1936.) 12s. 6d. net.

MR. LEWIS introduces his excellent study of infant speech somewhat dramatically by reminding us how, exactly half a century ago, Max Müller's saying "No thoughts without words" left linguistic studies somewhat in the air. To some, the aphorism went too far; to others not far enough. For the psychologist it was going too far, for obviously symbolic thought without words does occur. Linguistically it did not go far enough, for words mean more than ideas, and in their most important function they are as much a form of human action as any type of bodily behaviour.

To-day, linguists are faced by a similar dilemma. Once we recognize with Mr. Lewis that "language is a form of activity, a mode of human behaviour, perhaps the most important" (p. 5), the question arises: Can we treat language as an independent subject of study? Is there a legitimate science of words alone, of phonetics, grammar and lexicography? Or must all study of speaking lead to sociological investigation, to the treatment of linguistics as a branch of the general science of culture? If the earliest and most fundamental function of speech is pragmatic—to direct, to control and to correlate human activities—then obviously no study of speech except within the "context of situation" is legitimate. The distinction between *language* and *speech*, still supported by such writers as Bühler and Gardiner, but dating back to De Saussure and Wegener, will have to be dropped. Language cannot remain an independent and self-contained subject of study, once we recognize that it is only the general norm of human speech activities. Finally, we shall have to decide whether, with some recent German psychologists, we have to assign three separate functions to speech: the expressive, the evocative, and the representative; or whether we must be satisfied with the admission that speech has only one main function, that of pragmatic control, of co-ordinating human action; while all the other manifold uses and aspects of language are derivative.

The dilemma of contemporary linguistics has important implications. It really means the

decision as to whether the science of language will become primarily an empirical study, carried out on living human beings within the context of their practical activities, or whether it will remain largely confined to deductive arguments, consisting of speculation based on written or printed evidence alone. The first view would insist on drawing the material of linguistics from the observation of infant speech, from the study of pathological phenomena in aphasia, from fieldwork on the actual use of language by the various strata of civilized society, and among so-called primitive peoples.

The grammarian and the lexicologist may have in future to abandon their comfortable, two-dimensional world of parchment and paper, and either go into the field, or else rely on material documented not only by words, but also by those aspects of human life, activity, and social organization by which the use of words is determined. The present reviewer, like most modern anthropologists, would plead for the empirical approach to linguistics, placing living speech in its actual context of situation as the main object of linguistic study.

Mr. Lewis is not too dogmatic in the excellent theoretical introduction to his book. He gives there an impartial summary of most modern theoretical work. He himself, however, takes the empirical view that "the main function of language in human life as the mediator between man and man" must be taken as the guiding principle in any linguistic inquiry.

A cavilling critic might note some omissions in his choice of authorities. The absence of any reference to the work of Philipp Wegener, one of the forerunners of the modern movement; or to the American psychologist, G. H. Mead, who perhaps was the first clearly to formulate the principles of pragmatic symbolism; the relatively small space given to the work of Jespersen and Piaget; and the omission of John Dewey's most important contribution, that is, of Chap. v in "Experience and Nature" (1925), might be remedied in a future edition. On one or two formal matters I should like to suggest also an amendment. Thus to state that "speech is an instrument, a tool" is not, as the author supposes, a useful simile, but, like all analogies, an unnecessary handicap. Speech, obviously, is not a tool, but a habit, a standardized type of activity of the human organism. It is, therefore, not to be classed with the material products of man, but rather with the other modes of active human adjustment to the

nvironment and to the mechanisms of culture. Again, Mr. Lewis speaks of "language as an institution". Whatever meaning be given the word 'institution', the label again brings language as a fixed product into the realm of material achievements and leads us away from the study of speech customs within the living context of human activities.

But these are minor criticisms, and they are found only in the theoretical preliminaries of Mr. Lewis's treatise. When he comes to work, and enters his empirical laboratory, all the minor misconceptions vanish. Throughout, he studies the child's speech habits within the circumstances in which they occur. He conducts, in fact, all his observations, in the only admissible manner: he investigates *speech* and not *language*; and investigates it, not as a detached, purely linguistic transfusion of meaning, but as a means of action on adults by the child and conversely the influence of speech and other activities of the grown-up on the child.

This makes the author recognize that to regard the child's spontaneous utterance as merely 'expressive' in its function is erroneous. In fact, through the whole range of the author's observation, the distinction between 'expressive', 'evocative' and 'representative' falls to the ground. Mr. Lewis's results show that the only correct treatment is to study the total situation: the vocal

act of the child, which is linked up with the circumstances; and the reactions of the adults which respond to the child's pre-linguistic activity. The meaning of such a vocal act can only be defined as the change produced by the child's utterance in mobilizing its social environment, and making the adults obey its wishes. Obviously, an utterance like this is at the same time expressive, in that it corresponds to the child's feelings of discomfort or anxiety; it is representative, in so far as it is linked up with the situation; and it is evocative in so far as it makes the elders respond to the child's utterance. "Throughout all this the child will tend to use his cries more and more as an aid to the rest of his behaviour, and even as a substitute for it. . . ." In other words, from the very beginning, the human being uses his voice in prearticulate and later on in an articulate sense, in order to achieve, through the assistance given him by others, what he cannot do through his own bodily activity.

The work of Mr. Lewis is in many ways a great advance on all previous experimental studies on child speech and a valuable contribution to the theory of language. In his use of older sources, he is judicious, critical and comprehensive. In the setting of his own observations, he has taken his inspiration from the most scientific, that is, the most empirical point of view in modern linguistics.

Elementary Chemistry and its Presentation

New Practical Chemistry:

Fundamental Principles applied to Modern Life. By Prof. Newton Henry Black and James Bryant Conant. Pp. xi+621. (New York: The Macmillan Co., 1936.) 7s. 6d.

New Laboratory Experiments in Practical Chemistry

To accompany Black and Conant's 'New Practical Chemistry'. By Prof. Newton Henry Black. Pp. x+193. (New York: The Macmillan Co., 1936.) 5s.

THESE are welcome and important additions to the large number of text-books which deal with the fundamental principles of chemistry and their mode of presentation. Anyone still unconvinced that a knowledge of the fundamental principles of an ever-expanding science and some of their applications may not be a part of a general education might do well to make a detailed study of

these books, one of the authors of which is a distinguished organic chemist, well known in Great Britain, and president of Harvard University.

Much difference of opinion exists among those occupied with the teaching of elementary chemistry concerning the method of presentation. Unlike the authors, some prefer to adhere, so far as possible, to a more or less historical method, and to leave any consideration of the developments of the subject during the last twenty-five or thirty years to a later stage of the student's training. This has the disadvantage that the student who does not continue the more detailed study of the science has little knowledge of the structure of the atom, by which the properties of the elements and the structure and properties of chemical compounds are more adequately explained.

The presentation of the fundamental theories and facts of chemistry by the authors is excellent. Perhaps, at times, it is too didactic, and formulae

of compounds are stated before any description of the compounds is given. This might cause difficulties for the student who reads without the guidance of a teacher. But the books are not intended for home reading. Even the title of the larger volume, dealing with the more theoretical side of the subject, indicates that chemistry is a practical science, and the companion volume gives a comprehensive series of experiments to be carried out *pari passu* with the theoretical instruction. These not only include qualitative and quantitative exercises of the usual type prescribed for the beginner, but also experiments on soil testing, colloids, textile fibres, blue prints, dyeing, paints, food components of milk and identification of simple compounds. An elementary knowledge of such subjects might be frowned upon as being too technical to form part of general education; but it does provide possible stimuli on which later interest, whether for profit or leisure, may depend. It is no mean achievement to give such information without in any way sacrificing the accurate presentation of the essential facts and theories of chemistry.

It is rare to find elementary text-books so stimulating as these, and they would be unique if they were entirely free from faults. Some chemists would not agree with the authors'

explanation of the apparent dual valency phosphorus, and perhaps many teachers would hesitate in the first year of a student's training to give so detailed an account of Bohr's theory of spectra. From the teacher's point of view, however, it is important to realize that the authors show it can be introduced without much difficulty.

The authors state that they have "enriched the treatment by exceeding the factual requirements of the College Examination Board". It is to be hoped that this is the case, because the books are so comprehensive in subject-matter. This ranges from the early history of the science to atomic structure, from the "New Periodic Law" to radioactivity and transmutation of the elements, and from coal and oil to dyes, paints and vitamin. All these are apparently to be studied in one year and presumably the student takes other subjects besides chemistry. Perhaps American students for whom the books are primarily written, work harder than British students. Even if the use of these books is merely a candidate for a college entrance examination, he is fortunate in having the fundamental theories and facts of chemistry and some of their applications presented to him in so fascinating a manner.

CHARLES S. GIBSON

Operational Symbolism in Mathematical Analysis

The Theory of Linear Operators:

from the Standpoint of Differential Equations of Infinite Order. By Harold T. Davis. (Monograph of the Waterman Institute of Indiana University, Contribution No. 72.) Pp. xiv + 628. (Bloomington, Ind.: The Principia Press; London: Williams and Norgate, Ltd., 1936.) 35s. net.

THE modern philosophy of physical science leans strongly to the view, so well expressed by a recent writer, that the concept is synonymous with the corresponding set of operations. The idea of mechanical imagery advocated by Lord Kelvin is thus being replaced by the notion of an operational process which accordingly presupposes the existence of a law of transformation. To mathematicians, this aspect has long been the subject of profound study, but not until comparatively recently has the idea permeated the theoretical domain of science.

The formal theory of operators is generally considered to have originated with Leibniz and Lagrange, whilst in Great Britain the subject was mainly stimulated by George Boole, who clarified

our fundamental ideas in both logic and mathematics. Then came the generatrix calculus which Laplace made the basic method of his "Théorie analytique des Probabilités". A further stage is the development of operational methods arose from researches in electrical communication, out of which came the once-spurned operations calculus of Oliver Heaviside, a self-taught mathematical man of science. Finally, Volterra and Fredholm laid the foundations of the theory of integral equations and, later, the calculus of forms in infinitely many variables out of which, from the modern study of the quantum mechanics and the properties of electrons, has sprung the matrix calculus.

These main divisions of the theory of operators are all discussed with some detail in Chap. I of the volume under review, which was written, as a result of considerable research, to provide an outline of the theory of linear operators and its manifold applications to general types of linear functional equations. The volume is published as a monograph of the Waterman Institute of Indiana University, and surveys the theory of linear

operators from the point of view of the theory of differential equations of infinite order.

The development centres round the generalized differential operator. Several chapters are devoted to the definition and properties of operators, namely, particular operators, operational multiplication and inversion, grades defined by special operators, etc. Some very interesting examples are given in this section illustrating the application of operational processes. These include such important problems as the development of the disturbing function in planetary motion involving Newcomb operators; the propagation of electromagnetic waves in which Silberstein's elegant operational solution is used, and finally the propagation of population by fission, to which the operational method of Rawles is applied. Chapters vi and vii are devoted to differential equations of infinite order with constant coefficients, and linear systems treated by the Heaviside calculus.

Illuminating chapters then follow on the Laplace type of equation of infinite order, in which

the coefficients are polynomials of bounded degree; the generalized Euler equation of infinite order; Fuchsian operators of infinite order, and the Volterra and Fredholm integral equations of infinite order, in which a full description of Lalesco's theory is given. The closing chapter is devoted to the theory of spectra and, after giving some important theorems on matrices concerning transformations, identities and Hermitian, the author proceeds to discuss the equivalence of the theories of quadratic forms and integral equations, and, finally, some general considerations on the continuous spectra of quadratic forms.

Throughout the text, which is very clearly written, many applications to science have been indicated, and an extensive bibliography is provided at the end for further reading. Those interested in the subject will be grateful to have, within one cover, so complete an account of the new operational symbolism which has become one of the important methods of extending the domain of mathematical analysis.

F. G. W. B.

A Text-book of Aerodynamics

Elements of Practical Aerodynamics

By Prof. Bradley Jones. Pp. v + 398. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 18s. 6d. net.

AS the author claims in the preface, this is a student's text-book of American origin, and as such is an admirable exposition of the subject. It gives worked-out examples in the text and further examples for the student at the end of each division. This is a principle that has always been advocated by educationists, but seldom followed by writers of books on aeronautical subjects up to the present day.

The author states, apparently as a recommendation, that he has avoided the use of the calculus except upon two occasions. It is a little surprising to find fear of this branch of mathematics in any modern scientific book, more especially one expressly written for students, who surely must be beyond the study of such elements of it as would have been necessary in such a book before they even reach the stage of studying aerodynamics.

The first few chapters, dealing with the aerodynamics of the aeroplane, are extremely clear and lucid, but they should have been followed by

the chapters on stability, control, etc., so as to read as one continuous argument. One would like to have seen more on skin friction, laminar and turbulent flow, and such matters, treated as lucidly as the rest of the aerodynamics in these chapters.

The chapter on stability infers that lateral stability is less difficult a subject than longitudinal stability, a statement with which few aeroplane designers will agree. The mathematical consideration of it in theoretically undisturbed air may be, but this is only the introduction to the real practical problem with disturbed motion.

The second half of the book is made up of accurate, but quite inadequate, chapters on subjects such as materials, instruments, meteorology, 'avigation' (American for aerial navigation) and aerostatics. These are good, so far as they go, but are very elementary in character, and out of balance with the treatment of the subject-matter of the earlier chapters.

In general, this is a book that should appeal to students in Great Britain, to be taken as additional reading, giving a rather different American outlook on the subject. Now that we have adopted the same units as used in the United States, it will be less confusing to the beginner.

Death from the Skies:

a Study of Gas and Microbial Warfare. By Heinz Liepmann (with the scientific assistance of Dr. H. C. R. Simons.) Translated from the German by Eden and Cedar Paul. Pp. 286. (London: Martin Secker and Warburg, Ltd., 1937.) 6s. net.

THE author of this sensational book claims to have received information from certain authoritative sources which it would be inexpedient for him to acknowledge; but there seems to be nothing new in his disclosures, and all the probable war gases which he lists as "pre-eminently suitable" can be found in any of the books that have been published on this subject. He believes that "hundreds of millions" will perish from gas in the war that is to come. "Just a minute or two of a hideous struggle for air, and then death—lucky, perhaps, if it is over so quickly. In former days men condemned to death were at least given time for a prayer. Not these, not these. They groan, they scream, they suffocate, they die."

We hear again of the same old gas bomb which, falling in Piccadilly Circus, would destroy all life between Regent's Park and the Thames; and amongst the "authorities" on whom he depends he even includes an entry in a record of the German Patent Office. He comes to the conclusion "that there is no protection against poison gas. Anyone who says such protection is possible is a liar." Similarly, there is no defence against bacteria; and, should war break out within the next few months, Germany will wage bacterial warfare, and we may expect glass flasks filled with cultures and contaminated rats dropped from aircraft by means of small parachutes.

The author is mistaken in saying that the British General Headquarters undertook costly chemical experiments before the outbreak of the Great War in the expectation that poison gas would be used. He is also misinformed in supposing that no known gas mask can protect against blue cross gas; and quite wrong in describing the Chemical Warfare Research Committee as a joint Allied organization, and in stating that (the British) General Thuillier succeeded (the French) General Curmer as head of the French State Commission for Gas Service. His description of the present condition of Germany is quite the most interesting part of the book—"a poverty stricken and dangerous land, a focus of unrest for Europe, in imminent danger of exploding—the explosion being prevented only by a reign of terror unexampled in history". Hitler, he thinks, will inevitably embark on expansionist adventures, and a decisive struggle between Britain and Germany must occur.

O. H. F.

The Journal of the Institute of Metals

Vol. 59. Edited by G. Shaw Scott. Pp. 323+22 plates. (London: Institute of Metals, 1936.) 31s. 6d.

In September last year, the Institute of Metals held its autumn meeting in Paris, and this volume includes the sixteen papers presented on that occasion, together with the Autumn Lecture on "The Scientific Organisation of Works" by Prof. Pierre Chevenard, scientific director of the Société de Commentry,

Fourchambault et Decazeville. This lecture is a remarkable and convincing account of the successful application of scientific methods throughout a large industrial concern.

A considerable proportion of the papers published in this volume deal with the alloys of aluminium. M. Gauthier describes the effect on the conductivity of super-purity aluminium of additions of those elements which may occur as impurities in commercial aluminium; Mr. N. D. Pullen presents an account of a new treatment for the production of reflecting surfaces on aluminium, while Prof. Portevin and Dr. Bastien treat the property of forgeability in a fundamental manner.

A lengthy paper by Atkinson and Raper provides up-to-date metallurgical information on the six metals of the platinum group, while Northcott discusses veining and sub-boundary structures in metals. Other papers deal with the creep of tin and tin alloys, fluxes for use in soldering, and the constitution of the alloys of cadmium and tin and of indium and lead.

Statistical Year Book, 1937, of the International Tin Research and Development Council

Pp. 206. (London: International Tin Research and Development Council, 1937.) 6s.

THE International Tin Research and Development Council has carried out a useful task in issuing a comprehensive statistical year book, which deals not only with production and trade but also with the varied aspects of consumption. The use of tin in the automobile industry on one hand (8 per cent of the total world consumption) and in the canning industry on the other (50 per cent of the total) are indications of the widespread importance of this key metal. In spite of this, the production is very localized and about 85 per cent of the output comes now under the control scheme. Of the total world output in 1936 of 179,600 long tons, Malaya produced 66,806; the Netherlands East Indies 31,546; Siam 12,678; Bolivia 24,074; Nigeria 9,529 and China 10,664 tons. The greatest consumer, the United States, had a home production (including Alaska) of 87 tons, and the great European users have similar, tiny supplies only.

L. D. S.

The Technology of Aluminium and its Light Alloys

By Prof. Dr. Alfred von Zeerleder. Translated from the second German edition into English by A. J. Field. Pp. x+301. (Amsterdam: Nordman Publishing Co.; London: Crosby Lockwood and Son, Ltd., 1936.) 21s. net.

THE original German edition of this book was published in 1934, and a second edition was found necessary in less than twelve months. From this second edition Mr. Field has prepared the present translation, and has also brought the text rather more up to date. The book gives in condensed form the essentials of the working of aluminium and its alloys, the object being to bring home the merit and possibilities of aluminium to a wide circle of user and potential users. This purpose it fulfils admirably.

Greenland Culture. (2) The Eskimo*

THREE reports issued recently by the Commission for Scientific Research in Greenland deal with the culture of the Eskimo in East Greenland.

(1) *Kangerdlugssuak District*. An expedition of the Scoresby Sound Committee, of which Einar Eikkelsen was in charge and Magnus Degerbøl responsible for the archaeological investigation, examined the coast from Cape Dalton to Kangerdlugssuak, an area of great interest, as it is situated between the Angmagssalik Settlement in the south and the former Eskimo area of settlement in north-eastern Greenland from Scoresby Sound northwards. Before 1932, this region had been traversed only by the Amdrup expedition of 1900, which found a number of deserted Eskimo habitations, graves, tent-rings, etc., at the mouth of Kangerdlugssuak, but no remains from Kangerdlugssuak to Scoresby Sound, nor north of Cape Dalton to Dunholm, where, however, Eskimo remains existed. The present expedition confirmed this result, and it was only at Miki's Fjord, a few kilometres east of Kangerdlugssuak, that it was possible to prove former habitation. An inference that Irringer's Fjord was once the site of a habitation has later (1935) been proved to be correct.

Miki's Fjord is well suited to habitation. Here a ridge runs north-south, with terraces sloping to the south. A firm rocky ledge affords room for movement and building, with easy access to the sea. The only drawback is an absence of fresh water. On this terrace were five sets of house ruins, at different levels, the lowest being the largest and best preserved, though there is reason to believe that the smaller were parts only of houses originally larger. All the houses, with one exception of indeterminate shape, were rectangular. The objects found in the houses were essentially of the same culture period, and belong to the Inugsuk culture. The number of skeletal remains found in the house, together with the secondarily formed small houses, suggests that the population did not emigrate, but perished in their homes, possibly from malnutrition due to a lack of vegetable food. Animal food was evidently plentiful.

A woman's grave found on a small headland is one of the largest grave finds in Greenland, and contains several objects not known from other finds. An entirely new element, not previously known in Eskimo culture, is eighty-four beads, small white circular disks of mussel shell, while a needle case containing two needles of walrus ivory is the first example of a bone sewing needle from Greenland. An explanation put forward by Th. Mathiasen of the distinctive character of certain of the cultural objects is that the length of occupation gave rise to independent development.

The character of the remains and deposits shows that the occupation was one of considerable length. Immigration probably took place at the end of the fifteenth, or beginning of the sixteenth, century; and occupation, it is thought, may have lasted until so late as the eighteenth century.

(2) *Frederik VI's Coast*. An expedition in 1931-33, of which Knud Rasmussen was leader, made a study of former Eskimo settlements on this coast between Prince Christian Sound on the south and Ikarsuaq, the boundary of the Angmagssalik district, on the north, with the purpose of determining the number and character of the Eskimo settlements which were known to exist, but of which exact information was lacking. As many settlements as possible were inspected, and a few excavations were made. From all sources, including those already in print, as well as from information received, three hundred and eighty-two settlements were recorded in eleven regions. In 1931 Erik Holtved excavated eleven house sites, producing seventy-two artefacts, and in 1932 Th. Mathiasen excavated twenty-one ruins, producing 526 specimens.

The house types fall into the following categories: (1) small, rounded, and much overgrown and flattened-out houses; (2) small, four-sided, partly flattened-out houses; (3) large, four-sided, partly overgrown houses; (4) houses known to have been inhabited in the nineteenth and twentieth centuries.

The most important site investigated was Ruinneset on Skjoldunge Fjord. Here Knud Rasmussen discovered a great house complex. From this site alone 329 specimens were obtained.

In regard to the character and succession of cultures, it would appear that the earliest house ruins on this coast are probably contemporaneous with the earliest houses in Angmagssalik, and belong to the end of the fourteenth, or beginning of the fifteenth, centuries. They are small, round,

* The Scoresby Sound Committee's 2nd East Greenland Expedition in 1933 to King Christian IX's Land—The Former Eskimo Habitation in the Kangerdlugssuak District, East Greenland. By Magnus Degerbøl. (Meddelelser om Grønland, Bind 104, Nr. 10.) Pp. 48+1 plate. 2.50 kr.

6 og 7 Thule-Expedition til Sydøstgrønland 1931-33—The Former Eskimo Settlements on Frederik VI's Coast. By Thorkel Mathiasen. (Meddelelser om Grønland, Bind 109, Nr. 2.) Pp. 68. 2.50 kr.

The Eskimo Archaeology of Julianehaab District, with a Brief Summary of the Prehistory of the Greenlanders. By Thorkel Mathiasen. In collaboration with Erik Holtved. (Meddelelser om Grønland, Bind 118, Nr. 1.) Pp. 141+4 plates. 7.00 kr. (København: C. A. Reitzels Forlag, 1936.)

The first article appeared in NATURE of July 10, p. 52.

and dug down into the ground, with poorly built walls, paved floors, sunk passages and often a cooking extension. Sometimes two or three are built together, forming a clover-leaf shaped complex. Their culture shows evidence of some whaling. There are no glass beads. The culture is of the same type as the Angmagssalik, and belongs to the Inugsuk culture.

The seventeenth-eighteenth century house, of which sixty small, and seventy-seven large, were seen, is distinctly four-sided. At first small; later, in the eighteenth century, it becomes the large common house, which seems to have been introduced by a migration from the west coast, reaching as far as Angmagssalik. Houses of this type were seen at fifty-one settlements. The culture is particularly well displayed in the finds from Ruinasset. It is derived from the contemporary South-west Greenland culture, but with a special south-east coast stamp. This find is given a special character by the many drilled seal jaws.

Fifty-six houses on this coast are known to have been inhabited in the nineteenth century, or later. Records of this period were made on the voyage by W. A. Graah in 1829-30, when 536 Greenlanders lived here in summer. The movement to the west coast had already begun, the last southeasters moving to the southern part of the west coast in 1900. At the present time, it is visited occasionally only for sealing.

(3) *Julianehaab District*. In the course of an expedition sent out by the Commission in 1934 a comprehensive survey was made of the Julianehaab district, the most southerly part of Greenland's west coast, and its most fertile and thickly populated area. It forms a connecting link between East and West Greenland, and was the site of the principal Norse settlement. The main interest of the expedition was the investigation of early Eskimo settlement, of which very little systematic knowledge was previously available.

• It is now known that there are two hundred and forty-six places in the district where there have been Eskimo winter settlements. Of these, one hundred and thirty were visited. Excavation was possible on four sites only. Here fifty-six house ruins, four hundred square metres of midden, and twenty-three graves were examined, producing 1,808 specimens and fifty-seven skeletons. The house types are an early group of round or rounded small houses, sometimes two or three built together with a common passage; two types of the seventeenth-eighteenth century, distinctive, rectangular with a high stone wall and a sunken passage at right angles to the house, large; but the later type small; and fourthly, the nineteenth century house, small, rectangular, with high stone and turf walls and a passage in prolongation of the

longitudinal axis, often with a bend and not sunken, and with a kitchen or storehouse as an offset in the angle. This last is the type now in use, though it is being displaced by wooden houses.

The conditions for the preservation of cultural objects in the Julianehaab district are adverse in the extreme, owing to the succession of frost and thaw and the percolation of water. As a result of this, most of the ruins contained no bones or wood.

In the houses of the earliest type, most of the objects are of the kind known from other sites in Greenland and belonging to the Inugsuk culture. Among the most interesting and important were the lamps, which by their varying form afford a guide to chronology. Those with wick-ledge or knobs are a characteristic type of the culture. A number of objects of Norse origin probably represent spoil from the houses of the Norse settlement, which were deserted when the settlement decayed soon after the first appearance of the Eskimo in 1379. The earliest Eskimo culture of the District may be dated as lying within the period 1350-1650. Early settlement was invariably, so far as observed, half-way up the fjords, the situation most favourable for ice hunting. The principal quarry, as shown by the bones from the sites, was the seal, but the caribou and the whale were of importance.

The finds of cultural objects from the seventeenth-eighteenth century houses do not differ essentially from finds from other parts of Greenland. Glass beads were found in most of the ruins, but in no great numbers. The principal varieties are the large opalescent, the large faceted—blue, yellow and colourless—a large black, a large rather flat dark blue, and a cylindrical bead, red with white longitudinal stripes. Although the culture as a whole compares with that of West Greenland, it has in its harpoon-heads, arrow-heads and lamps an older stamp, as indicative of an out-of-the-way situation. The same old-fashioned types are recognizable at Angmagssalik, the similarity appearing in a relatively large number of objects, such as salmon spear, fish hooks, pendants, etc. The animal bones show that sealing had been the principal occupation; but the inhabitants also hunted whales, caribou, white-whales, bears, foxes and fowl. In certain periods there have been many fish, especially cod. There is also a surprisingly large number of dog bones, but no proof of sledge traction.

The development of the kayak, and the consequent increased utilization of sea locomotion for hunting and fishing, led to a diffusion of settlement, the number of small settlements increasing markedly. In the following period of the nineteenth and twentieth centuries, however, the number of

small settlements declined, and large settlements again prevailed, in order that the population might be near the centres of commerce and industry, which grew up with European settlement. The introduction of wooden houses put a further check on the nomadic habits of the people.

The mummy caves at Querrortut were also investigated. Though much disordered by a previous party of archaeological investigation, remains of desiccated bodies were found, which may be attributed to interment and not to incarceration and death from starvation. The occurrence of grave goods points to the pagan period, and tentatively a sixteenth century date is assigned.

Summarizing his survey of prehistoric Eskimo culture in Greenland, Dr. Mathiasen reconstructs their ethnic history by attributing to them an origin in arctic Canada, whence they came about a thousand years ago, with whale-bone houses and the Thule culture, to settle in the Cape York District. Thence they passed southward over Melville Bay to northern West Greenland, where they remained for several hundred years, encountering the Norsemen travelling northward, and changing the Thule culture into the Inugsuk

culture. In the fourteenth century the growth of population forced them to seek new hunting fields. South Greenland was populated in the course of this century, the Norsemen being overrun. A group of Eskimo wandered around Cape Farewell to the east coast and far to the north along the coast. In the seventeenth century Polar Eskimo migrated north about Greenland and mixed with north-east Greenland's early population. Shortly afterwards, West Greenlanders reached Angmagssalik, while a small remnant of survivors from the first immigration to the east coast at Kangerdlugssuaq died out, as also did the inhabitants of north-east Greenland. In West Greenland, however, the population grew rapidly, helped by Danish settlement; while at Cape York there was still a remnant of the old Thule Eskimo, helped by a new immigration from Baffinland.

On the general Eskimo problem, Dr. Mathiasen expresses the opinion that it cannot be solved in Greenland. He is, however, unable to accept K. Birket-Smith's Caribou Eskimo theory, which makes Eskimo culture a link in a circumpolar inland culture, first created in the central parts of arctic Canada. The Thule culture points to Alaska and possibly Siberia.

The Halle Academy, 1652-1937

THE Kaiserlich Deutsche Akademie der Naturforscher at Halle has recently celebrated the two hundred and fiftieth anniversary of the granting of its charter. In 1652, soon after the end of the Thirty Years' War, there was founded by four physicians, in the Reichsstadt of Schweinfurth, a scientific society under the name of *Academia Naturae Curiosorum*. The principal founder and first president, Johann Lorenz Bausch, had studied in Italy and become acquainted with the local academies of that day, and especially with the Lynceorum Academia, now Accademia Reale dei Lincei; he was also influenced by the writings of Bacon of Verulam. In 1677 the Emperor Leopold I recognized the society as the Academy of the Holy Roman Empire, and ten years later the same prince bestowed upon it considerable privileges and the title of *Sacri Romani Imperii Academia Cæsareo-Leopoldina Naturæ Curiosorum*. Arms were granted, with the motto: "Nunquam otiosus"; the president and the editor of the ephemerides received golden chains of office; they and their successors became counts palatine of the Holy Roman Empire; as such they could legitimize bastards, confirm the liberation of

slaves and perform other legal functions. They could, moreover, confer the titles of doctor, licentiate, master and bachelor, in the faculties of medicine, philosophy and laws; they could even appoint poets laureate. The doctorates so conferred were to secure the same privileges as those given by the universities. The publications of the Academy were exempted from censorship and protected as to copyright.

The Academy has survived the Empire from which its privileges were derived; these privileges were never abolished, but their exercise fell into abeyance. So did the curious custom, recognized in the imperial charter of 1687, of giving 'symbolic' names to its members; thus the first president was known as Jason I, his successor as Argonauta I. Meetings also fell into abeyance, and the activities of the Academy became restricted to the publication of a scientific periodical and to the administration of its library and museum. The location of the latter at first changed with that of the president, until the Academy became definitely established at Halle. Its natural history collections have been dispersed, but its library remains rich in valuable periodicals, of which a recently

published catalogue enumerates some 3,650 items ("Verzeichnis der periodischen Schriften der Bibliothek der Kaiserlich Leopoldinisch-Carolinisch Deutschen Akademie der Naturforscher, Halle (Saale)", 1937). The most important work of the Leopoldine Academy has been the publication of a journal, *Miscellanea curiosa medico-physica Academiae naturae curiosorum sive Ephemerides Germanicae*, started in 1670 and probably the oldest scientific periodical. In the eighteenth century this valuable journal changed its name to *Acta physico-medica* and then to *Nova acta*; in 1932 a new series, *Nova Acta Leopoldina*, was started.

Various scientific funds have been lost as the result of economic upheaval, but a bequest by Christian Andreas Cothenius, the physician of Frederick the Great, is still operative; in accordance with it, a medal is from time to time awarded for scientific research. A second medal and a research fund was more recently instituted in memory of Auguste Henri Forel, the biologist and sociologist.

It will be seen from the above account that in modern times the Casareo-Leopoldina has received no official protection, nor been subject to governmental control. It is one of the oldest of scientific societies; the Royal Society has indeed the older charter, the Lincei Academy the longer history, albeit not so continuous. The present year is the two hundred and fiftieth after the granting of privileges by Leopold I, and this anniversary was celebrated at Halle on May 28-30. The commemoration was attended by representatives of numerous universities, academies and societies, both German and foreign, who were welcomed in the aula of the University by Prof. E. Abder-

halden, the president of the Academy, who has done much to stimulate its activities. His opening address, a historical retrospect, was followed by official congratulations from the rector of the University and the mayor of the city. Then came brief speeches on behalf of the Royal Society of London, the Accademia delle Scienze of Bologna, the Accademia dei Lincei of Rome, the Académie of Vienna, Amsterdam, Copenhagen, Tokyo, the American Academy of Arts and Sciences, at Boston, the Kartell of the German Academies (Berlin, Göttingen, Munich, Leipzig, Heidelberg), etc. It was announced that a sum of 44,000 marks has been collected from numerous donors, to be used henceforth as a research fund.

A very noteworthy lecture was then delivered by Prof. Hans Spemann, of Freiburg, on his recent researches concerning the nature of animal development. Finally, the Cothenius medal, referred to above, was awarded to Profs. Dante de Blas (Rome), Ostertag (Tübingen), Franz Volhard (Frankfurt), G. Barger (Edinburgh), Max le Blanc (Leipzig), Armin Tschermak-Seysenegg (Prague) and Eugen Fischer (Berlin). In the evening there was a banquet with a few speeches. Next day further lectures were given; there was an admirable performance of an operetta in the municipal theatre, and a pleasantly informal reception by the Oberbürgermeister; the third day, Sunday, was devoted to an excursion in the country.

In connexion with this very successful celebration, there have been printed the above-quoted catalogue of periodicals in the Academy's library and a well-illustrated *Festgabe* containing three historical essays and Prof. Spemann's lecture.

International Agreement for the Regulation of Whaling

THE International Agreement for the Regulation of Whaling, which was published on June 23, marks an important stage in the development of whaling regulation. It was the work of a conference at which eleven Governments interested in whaling participated. They met on May 24, and sat almost daily until June 8, when the Agreement was signed. The drastic nature of its provisions are eloquent of the practically world-wide conviction that whaling can be saved from collapse only if it is rationally regulated: while a note under the title "Final Act", which is appended to the Agreement, indicates that the possibility is recognized that actual restriction of

whaling effort may prove necessary if that end is to be achieved.

In the early stages of modern antarctic whaling, the scale on which destruction of the whale stock was wrought made the need of regulation apparent. The Falkland Islands Government, which controlled practically all antarctic land stations, gradually built up a system of regulations and—a feature not yet attempted for whaling as a whole, restriction of the number of whaling vessels—which, while provisional in character owing to lack of information, may be said to have proved adequate until the late 'twenties, when the building of ships capable of working up the whales

in the high seas took the main body of whaling into international waters. The Norwegian Whaling Law of 1929 imposed on Norwegian whaling the provisions of the Falklands regulations except imitation, and added the power to prohibit Norwegian whaling in tropical and subtropical waters.

The Geneva Convention of 1931 followed the lines of the Norwegian law, though without provision for closing areas to whaling. This convention expressed the maximum to which at the time general agreement could be secured. It was recognized that whaling, being mainly outside territorial waters, could be dealt with only by common action, and the inauguration of international treatment was the first object to be attained. The majority of whaling countries adhered to it, and put its provisions into force by legislation which, with the increase of knowledge, tended to go farther and to be more definite than the convention it implemented. Limitation of production was effected by agreements within the industry in several recent seasons: but from various causes these agreements became increasingly difficult to reach, and the International Conference accordingly became necessary.

Space will not permit of any detailed account of the measures taken so far, but it will be useful to summarize the position in the antarctic when the Conference opened, among the countries adhering to the Convention. Only baleen (whalebone) whales were dealt with. Among these Right whales (*Balaena glacialis*), the numbers of which had been reduced almost to disappearance, were protected completely. Protection of other species was partial. It was illegal to kill immature whales, or cow whales with calves, and lengths were laid down below which for the purposes of the regulation Blue (*Balaenoptera musculus*) and Fin (*B. physalus*) whales were to be considered immature. The number of whales killed to afford a given quantity of oil was kept as low as possible by requiring the utmost practicable utilization of each carcass. The pay of gunners had not to depend merely on the number of whales shot. Full records had to be kept of the whales killed and the oil produced. Other provisions, such as the partial protection of the Humpback (*Megaptera nodosa*) in the Falkland Islands Dependencies, were to be found in certain cases.

The agreement now reached affords complete protection to the Grey whale, *Rhachianectes glaucus*, as well as to all Right whales. The lengths below which Blue and Fin whales may not be taken is advanced from 60 ft. to 70 ft. and from 50 ft. to 55 ft. respectively. The mean size of these species in the antarctic at first maturity was determined in the "Discovery" Investigations as

74 ft. 2 in. for male and 77 ft. 9 in. for female Blue whales, and 63 ft. 8 in. for male and 65 ft. 7 in. for female Fin whales. The new limit is thus a marked approach towards the actual mean size at maturity. For the first time, minimal size limits were laid down also for Humpback and Sperm whales (*Physeter catodon*); namely, 35 ft. in each case, this length having a similar relation to the size at first maturity of Humpback and male Sperm whales, according to the best available information and protecting female Sperm whales. Those familiar with the sizes of the whales taken in commercial operations will realize the large body of whales these limits will preserve to reproductive size. It may be noted also that the limits will apply to shore stations.

The seasons for whaling are restricted. Antarctic whaling, that is, whaling south of 40° S., will take place only from December 8 until March 7, though there is a short extension for next season only; and no shore station may operate for more than six months in the year.

Lastly, pelagic whaling is prohibited over enormous tracts of sea. The whole Atlantic and Indian Oceans north of lat. 40° S. are closed to it, as is an extensive equatorial belt of the Pacific. The objects of this provision are the protection of calving grounds and the prevention of the destruction of whales when in their least productive condition. It may be possible in the light of further information more narrowly to define these areas, but their present extent guarantees a valuable protection.

The requirements of furnishing statistics and the regulations as to the payment of gunners are as in the previous practice of Norway and Great Britain.

The Agreement is for the coming season only, but there is provision for its year-to-year extension. It has been signed for the Union of South Africa, the United States of America, the Commonwealth of Australia, Germany, the United Kingdom of Great Britain and Northern Ireland and the Dominions, etc., the Irish Free State, New Zealand and Norway. It is to be hoped that other States will adhere to the Agreement: in particular, the adhesion of Japan would make its operation almost world-wide. The "Final Act," appended to the Agreement shows that the possible desirability of changes and extensions of its terms is fully recognized, and it is recommended indeed that next year, after the experience of a season's working, another conference should be convened to consider the Agreement in these respects. A very welcome recommendation is that Governments should take powers to regulate the methods of killing whales. There is reason to think that this would be in the interests of both economic working and humanitarianism.

Obituary Notices

The Marchese Marconi

THE death of the Marchese Marconi from heart failure on July 20 deprives us of one who had taken the leading part in the development of world-wide communication. It is difficult to exaggerate the importance of his discoveries and the great effects they will have on the future history of the world. For communication purposes, he took the lead in helping to abolish space; and it is to be hoped that this, in the course of time, may result in the abolition of differences in language and even limitations of race. When sound and television are perfected in broadcasting, the outcome of early experiments in radio, life will surely be made easier for the masses, and Marconi's name will be kept green for hastening the advent of this blessing to humanity.

The early history of a great inventor is instructive; and luckily we have many accounts of Marconi's early life. One of the most interesting is the book by R. N. Vyvyan, formerly engineer-in-chief to Marconi's, entitled "Wireless over Thirty Years". For many years, Vyvyan was in close personal touch with Marconi and took a leading part in the great transatlantic transmission experiments.

Guglielmo Marconi was born in Bologna on April 25, 1874, his father being an Italian country gentleman and his mother the daughter of Mr. Andrew Jamieson, of Daphne Castle, County Wexford, Ireland. He was the younger of two brothers and was privately educated at Bologna, Florence and Leghorn. He attended Prof. Rosa's lectures on physics and studied the works of Prof. Righi. He was familiar with researches that had been made on Hertzian waves. While still a student, he was firmly convinced that just as flashes of light can be used to send signals by means of a heliograph, so, in an analogous way, electric waves could be used for signalling.

Marconi's earliest experiments were made in 1894 before he was twenty-one years of age. He used an induction coil as a Hertz emitter, and, at first, used a ball discharger of the type designed by Righi. It consisted of four brass balls separated by small gaps, immersed in 'Vaseline' oil. He connected one terminal of the secondary of the induction coil to a metal cylinder elevated to the top of a pole, and the other to a metal plate laid in the ground. He thus produced an elevated aerial which discharged across the spark gap to earth. At the receiving end he erected a similar capacity at the top of a pole and connected it to earth through a Branly coherer. He improved the design of this coherer, making it much more sensitive than anything previously made. In 1895 he employed metal cubes, the length of an edge being one foot. With this apparatus he was successful in receiving signals up to a distance of thirty metres. Doubling the height of the poles to four metres, he found that he could transmit to a hundred metres

and quadrupling the height to eight metres, he transmitted to a distance of four hundred metres. He next increased the cubes so that their edges were about 3 ft. 3 in. in length. With this new aerial he was able to record Morse signals up to distances of about one and a half miles. He also tried the effect of concentrating the waves by means of large metal parabolic reflectors. This experiment was the forerunner of the beam aeriels which came into use in later days when short electric waves were proved to be practicable.

In 1896, Marconi came to England and took out a patent, the first ever given for radio-telegraphy. In July of that year, Mr. Campbell Swinton introduced Marconi to Sir William Preece, the engineer-in-chief of the British Post Office. Sir William gave him every facility to carry out his experiments and with the help of the Post Office engineers, his system was successfully operated between the General Post Office and the Thames Embankment. The attention of the general public to the importance of Marconi's experiments was first attracted by the experiments carried out on Salisbury Plain, where reception over a distance of eight miles was demonstrated in the presence of officials of the Navy, Army and Post Office. In June 1897, Sir William Preece, in a lecture to the Royal Institution on "Signalling through Space without Wires", said that "Marconi had produced from known means a new electric eye, more delicate than any known instrument, and a new system of telegraphy which will reach places hitherto inaccessible". He also said that for shipping and lighthouse purposes it was a great and valuable acquisition.

In 1897, 'The Wireless Telegraph and Signal Company, Ltd.' was formed to acquire Marconi's patents. Three years later, the name was changed to 'Marconi's Wireless Telegraph Co. Ltd.' Marconi's next step was to erect a station at Alum Bay and another in Bournemouth. For this communication system he elevated his aeriels to a height of about 120 feet and used a ten-inch spark induction coil. The Isle of Wight station was inspected by Lord Tennyson and Lord Kelvin, the latter paying for two radio messages. One of these, dated June 8, 1898, was to Sir William Preece at the G.P.O., London, and the other to Sir George Stokes.

In 1898, Prof. Slaby, of the Technical High School, at Charlottenburg, wrote an article on the 'new telegraphy' in the *Century* magazine. He pointed out that by a simple, but extraordinarily effective, method Marconi had raised the power of radiation a hundredfold. In collaboration with Count Arco, Prof. Slaby developed the Slaby-Arco system, but the German national wireless system—known as the Telefunken System—was not founded until 1903.

In May 1898, at the request of Lloyds' Corporation, apparatus was installed at Ballycastle and Rathlin Island in the north of Ireland. Uninterrupted

communication was obtained, the lighthouse keepers quickly learning how to use the apparatus. About this period, Marconi greatly increased the range of transmission by inserting the primary winding of a small air core transformer in the aerial, the secondary windings being split by a condenser, the outer ends being brought to the terminals of the coherer. These transformers were called 'jiggers', and their efficiency encouraged Marconi to attempt to communicate across the Channel. The French Government gave permission to erect a mast at Wimereux. A corresponding mast was erected at the South Foreland Lighthouse and Marconi successfully transmitted messages on March 27, 1899. The Wireless Co. had established their works at Chelmsford and had erected a mast 150 feet high. Communication was affected between this station and Wimereux—a distance of 85 miles.

In the year 1900, the technical staff that the Wireless Co. had collected numbered only seventeen. Among them were Eccles, Erskine Murray and Andrew Gray, who was afterwards manager. In 1899, Prof. (now Sir Ambrose) Fleming had been appointed scientific adviser to the Company. The rapid increase in the range of radio communications had convinced Marconi that the curvature of the earth presented no obstacle to the extension of radio communication, and he decided to attempt to telegraph by his system across the Atlantic. In consultation with Fleming it was decided that the station for the transatlantic experiments should be built on the west coast of Cornwall. The site chosen was at Poldhu, on the west coast of the Lizard. In 1900, Marconi obtained his very important patent for 'tuned or syntonie telegraphy'. He used this method in his attempts to send signals across the Atlantic. He erected a station similar to Poldhu at Cape Cod in Mass., U.S.A. Unfortunately, the masts and aerial at Poldhu were wrecked by a storm, and a similar mishap at Cape Cod threatened to delay seriously the experiments. To save time when the Poldhu station was restored he went to Newfoundland and used a balloon to support his aerial. But as this was blown away, he used a kite as the support which, with great difficulty owing to a storm, was kept at a height of about 400 feet. He cabled to Poldhu to begin the pre-arranged programme, consisting of sending the Morse letter S (3 dots in succession) from 3 p.m. to 6 p.m. each day. On December 12, 1901, both he and his assistant repeatedly heard in their telephone the three clicks which proved that the electric waves had traversed the 1,800 miles separating St. John's from Poldhu.

In 1902, the site of a power station was chosen at Glace Bay in Canada, and when completed Marconi left England for Canada in an Italian cruiser, arriving on October 31, 1902. During the whole voyage he was receiving from Poldhu in the night time, but in the daytime he heard nothing after the distance was greater than 500 miles. When transmission was started, the early results were very disappointing. Later on, a site for a new station was found at Clifden, Ireland, and aerials were erected on a new principle Marconi had discovered. The Glace Bay

and Clifden stations were opened for unlimited public service in February 1908. During the Irish rebellion, the Clifden Station was put out of action and a new station at Caernarvon in Wales was used instead.

Prior to 1916 it was generally accepted that for long-distance transmission long waves were essential. But in 1916 Marconi began his wonderful experiments on short-wave transmission, the wave-lengths being only about a hundredth of those usually employed. Erecting a small transmitting station at Poldhu, and fitting a receiver to his yacht *Eletra*, he found in 1923 that with a wave-length of 92 metres excellent reception could be obtained up to about 1,200 miles. The outcome of his work was that the Government accepted the Marconi Company's proposals to use the short-wave beam system for Imperial communications and started building stations capable of working with Canada, South Africa, India and Australia. Later on, in 1931, Marconi turned his attention to the systematic investigation of waves only about one metre in length. Using these waves, a transmission system was put into successful operation between the Vatican City and the papal palace at Castel Gaudolfo.

To the end of his life Marconi retained the vigour of youth. His love for experimenting never waned, and he infected his colleagues with his enthusiasm. He worked hard and was very successful in applying his theories.

Marconi married in 1905 the Hon. Beatrice O'Brien, daughter of Lord Inchiquin, who had been lady-in-waiting to the Queen of Italy. The marriage was dissolved by decree granted at Fiume in 1924. In 1927 he married the Countess Beasi-Scali of Rome. He had one son and two daughters by his first wife and one daughter by his second.

During his lifetime Marconi's achievements brought him many of the highest honours which nations can bestow. His name is a household word all over the world. The patience and equanimity with which he bore the disappointing results obtained by many of his early laborious experiments will be for all time an encouragement to young engineering physicists.

Dr. H. H. Jeffcott

HENRY HOMAN JEFFCOTT, who died on June 29, was born in Co. Donegal in the year 1877. In 1895 he entered Trinity College, Dublin, from the High School, Dublin, and had a very distinguished career there. In 1897 he obtained a senior exhibition at the final freshman examination, and in 1898 he was first mathematical scholar. In 1899 he graduated with a senior moderatorship in experimental science and a junior moderatorship in mathematics and a moderatorship prize. He spent the next year in London, and in 1900 returned to Trinity College and entered the Engineering School, where he obtained his engineering degree in 1902 with honours in all subjects. In the same year he won the McCullagh Prize for a treatise on the theory of elasticity.

Jeffcott spent the next few years in the shops of Armstrong Whitworth and Co., Ltd., and as assistant

engineer with Siemens Brothers, and in 1905 went to the National Physical Laboratory and there became head of the Metrology Department. In 1910 he returned to Dublin as professor of engineering in the Royal College of Science for Ireland. In 1914 he became Dean of the College. During the Great War years his department was organized most successfully for the manufacture of munitions. In 1922 he received the degree of doctor of science of the University of Dublin. From 1918 until 1921 he was secretary to the Water Power Resources of Ireland Sub-Committee and took an active part in collaboration with Sir John P. Griffith, past president of the Institution of Civil Engineers, in the preparation of a scheme for the development of the water-power of the River Liffey. This scheme, though put on one side while the power resources of the Shannon were being developed, is now beginning to take practical shape under the aegis of the Electricity Supply Board.

In 1922 Jeffcott left Dublin for London on his appointment as secretary to the Institution of Civil Engineers, which position he filled until his death. His charming manner endeared him alike to his staff and the members of the Institution. He was very approachable and welcomed members who called on him, especially those home from abroad. His business ability and tact combined to bring to a successful conclusion many important negotiations with Government departments and public authorities. The recent reorganization of the Institution's activities brought much work to Dr. Jeffcott which the state of his health made very onerous. His early death, on June 29 at the age of sixty years, will prove a severe loss to the Institution and an irreparable one to those who had the good fortune to be his friends.

Though of exceptionally fine physique—Jeffcott was well over six feet in height and broad in proportion—he never took an active part in the athletic life of his college, though he thoroughly enjoyed a good game of tennis.

Jeffcott achieved considerable success as an inventor, being best known in this connexion through the Jeffcott direct-reading tachometer. He was the author of papers on the vibrations of loaded shafts published in the *Proceedings of the Royal Society* and *Philosophical Magazine*, and of papers on water resources and other engineering subjects.

Miss Dorothy Sladden

By the tragic death of Miss Sladden in consequence of a motor accident on Saturday, June 20, a severe blow was struck at the science of experimental zoology. Miss Sladden was one of those rare people on whom Nature has bestowed an inborn love of animals and a marvellous skill amounting to genius in keeping them in good health and in inducing them to breed. She had not had a university education, but she was taken to the Imperial College by her parents as an occasional student, because they saw no other outlet for her peculiar abilities which had manifested themselves since she was quite a young girl.

After passing through the regular undergraduate course, at my suggestion Miss Sladden took up the question of the heritability of acquired habit and carried out with indomitable perseverance a series of experiments on this subject which extended over five years. She showed that the stick-insect (*Carausius morosus*) which is a native of southern India but which has been imported into Great Britain and is readily obtainable from dealers, could be induced by a series of periods of semi-starvation to accept a food (ivy) which was at first repugnant to it, and that the offspring of such insects accepted ivy more readily than did their parents, so that after five or six generations, 100 per cent of the insects accepted ivy at the first opportunity. In this species, males occur only at long intervals and the ordinary female is parthenogenetic, so that the complications involved in crossing different stocks are completely avoided. Two of her papers on this subject had already been published by the Royal Society, and a third in which she dealt successfully with objections which had been made to her first two papers, was nearly ready when a cruel fate snatched her away. Fortunately, this paper will be completed by our mutual friend, Mr. H. R. Hewer, who assisted and advised her in statistical matters.

It may be justly said that Miss Sladden has demonstrated beyond reasonable doubt that functional inheritance is a reality; and this is the cardinal question in zoology, indeed in all biology. Once this conviction has gone home, the whole course of evolution becomes clear and doctrines like the recapitulatory theory of evolution which have been fiercely fought over, follow as a matter of course. That functional inheritance must be true is a conclusion which had already been accepted by leading paleontologists and systematists in the British and other great museums, but the distaste for it felt by a certain modern school of biologists is so great that they refused to accept any but direct experimental evidence in its favour. This has now been provided by Miss Sladden, and it is a feat which will make her name live in the annals of zoology.

E. W. MACBRIDE.

We regret to announce the following deaths:

Prof. E. B. Elliott, F.R.S., emeritus professor of pure mathematics in the University of Oxford, on July 21, aged eighty-six years.

Prof. W. T. Mather, professor of physics in the University of Texas, on June 14, aged seventy-two years.

Major Paul Murphy, formerly director of experiments, Chemical Warfare Station, Porton, on July 14.

Prof. S. C. B. Pennington, emeritus professor of agriculture in the University of Reading, on July 19, aged sixty-eight years.

Sir Charles E. Saunders, formerly Dominion cerealist, known for his work on the breeding of wheat in Canada, on July 25, aged seventy years.

Prof. Johannes Walther, emeritus professor of geology and palaeontology in the University of Halle, on May 8, aged seventy-seven years.

News and Views

Sir Denison Ross, C.I.E.

THE retirement of Sir E. Denison Ross from the office of director of the School of Oriental Studies in the University of London, which he has held since the establishment of the School in 1916, has evoked numerous tributes of appreciation of his work as scholar and administrator, as well as of personal regard, which culminated at the dinner at which he was entertained as guest of honour on July 26. The fact that seven thousand students have passed through the School in the twenty-one years of its existence is sufficiently impressive, when it is remembered that before it came into being there were virtually no facilities for oriental studies in London; but these figures give only a very imperfect idea of the importance of the School as an Imperial asset. By adding Africa and its languages to the Orient in the stricter sense of the term, the School not only covers a broader field of scholarship than any other single institution of its kind, but it has also become a much valued, and indeed an essential agency in the training of officials, missionaries and others, whose life-work is, or will be, among the less advanced races of the Empire. This breadth of outlook and sense of public responsibility in the orientation of academic studies is largely due to the qualities and experience which Sir Denison Ross brought to the task of organising and developing the work of the School. After a grounding in the study of oriental languages at Paris and Strasbourg, he travelled extensively in the Near, Middle and Far East, and acquired a knowledge of Asiatic languages and cultures no less extensive. This may be seen in his published works, which range from critical works of scholarship to appreciations of art and literature. Perhaps not the least scientifically interesting is a polyglot list of birds in Turki, Manchu and Chinese. No less important, however, than his gift of tongues was his educational and administrative experience during his thirteen years in Calcutta, which had proved and strengthened his ability to arouse enthusiasm for Oriental scholarship in others.

Prof. C. G. Cullis

At the end of last year, Prof. C. G. Cullis retired from the chair of mining geology which he had held at the Imperial College of Science and Technology, London, since 1930. He became a student demonstrator in the Geological Department of the College so long ago as 1890, and was thus a member of the staff for nearly half a century, having been professor of mineralogy before he was appointed to the chair of mining geology. Prof. Cullis's former colleagues and students, many of whom are scattered over all parts of the world, recently assembled at the College to present an album to him containing their signatures, and to record their appreciation of his work and influence. In this tribute the subscribers say:

"Generations of students will ever remember Professor Cullis as the ideal university lecturer. To few is given the skill to expound with such grace and effect the great truths of geology. We know the labour that is necessary for the attainment of apparent ease and simplicity: and here we see an apt example of *ars est celare artem*. But not only as a teacher will his students remember him: as a wise friend and mentor he was always accessible, and expert alike in directing their studies and in helping them to find their feet in the great world outside the College." In addition to the album, a cheque for the balance of the fund subscribed was presented to Prof. Cullis and a handsome electric clock to Mrs. Cullis and him jointly. Prof. Cullis has presented the cheque to the Governing Body of the College, with the suggestion that the income accruing from it should be used for the benefit of the mining geology department or students at the discretion of the professors of geology and mining geology department with the rector. The Governors have accepted this gift, and have resolved that the name of Prof. Cullis should be associated with the fund.

The Promotion of Peace

A petition to His Majesty's Government has been signed by a large number of distinguished people urging the Government to seek to avert the calamity of war by promoting an international inquiry into the fundamental causes of rivalry and unrest among the nations. The petition urges His Majesty's Ministers to take the initiative in this matter by inviting all other fully self-governing States, Dominions or Colonies to combine with Great Britain on equal terms in setting up expert commissions to ascertain and report upon the basic facts in regard to such questions as access to raw materials, and world markets, colonial development and the problem of surplus populations, foreign loans and credits, trade restrictions and international exchange. The signatories affirm their belief that if Great Britain showed an earnest desire to solve these problems, with full and impartial consideration of all just claims, her example would encourage the establishment of confidence and good will among the peoples of the world.

THE signatories of this petition include many heads of universities and colleges, more than one hundred fellows of the Royal Society, nearly as many distinguished writers as well as the archbishops, bishops and other Church leaders, and a number of members of Parliament. Representatives, individuals of all parties and officials of a large number of important organisations of all kinds throughout the country, have added their signatures, indicating the remarkable and extensive support which a representative body of opinion is prepared to afford the British

Government in the role of world peace-maker. The action already taken by the League of Nations, and approved by the Government, in promoting an inquiry into raw materials is obviously in line with the wishes of the signatories. The first essential step is to establish the facts in these matters beyond dispute, and the wisdom and urgency of this step are the more obvious in view of the refusal of certain countries to participate. If, in spite of such refusal, the British Government resolutely persists in a search for some way of reconciling the conflicting claims of different countries, convincing proof will be afforded of Great Britain's desire to promote peace based on a foundation secure because it is just.

Belfast Meeting of the British Medical Association

THE British Medical Association held its one hundred and fifth annual meeting at Belfast last week under the presidency of Prof. R. J. Johnstone, professor of gynaecology in the Queen's University of Belfast. The main theme of his presidential address, entitled "Some Thoughts on Medical Education", was medical education, undergraduate and post-graduate. As a university teacher and member of the General Medical Council, Prof. Johnstone was able to speak with authority from practical experience. He said that the critic of medical education generally assumes that the teachers should, at the end of the five years curriculum, turn out the general practitioner as a finished product, and blames them if they do not do so, although no one expects a finished surgeon, anatomist or pathologist at the end of this period. The specialist must know almost everything about his subject, the general practitioner must know something about almost every medical subject, and the course the latter has to pursue cannot be less difficult than that needed by the former. Although clinical study must have a considerable place in the education of the undergraduate, it is a fallacy to consider that clinical training is the be-all and end-all of medical education. There must be an adequate background of human anatomy, physiology and pathology provided by medical education. Prof. Johnstone also alluded to the existence of dreary lectures and dull teachers, and suggested that courses of instruction in the art of lecturing might be instituted for those appointed to teaching posts.

Nutritional Requirements of Pregnancy

At a joint meeting of the Sections of Obstetrics and Gynaecology and Nutrition, a discussion took place on the nutritional requirements of pregnancy. Sir Robert McCarrison said that the food essentials needed by the prospective mother are, in order of precedence: (1) milk and milk products; (2) whole or lightly milled cereals, particularly good wholemeal or standard bread, and oatmeal; (3) green and leafy vegetables; (4) root vegetables, particularly potatoes, carrots and onions; (5) fruit, including the tomato; (6) pulses; (7) eggs; (8) meat, including fish, fowl and glandular organs. To these should be added, in Great Britain, a daily teaspoonful dose of cod liver oil; a portion of yeast extract is a wise

precaution. Dame Louise McIlroy also stressed the value of fresh fruit and vegetables, herrings and wholemeal bread. She suggested that lessons and demonstrations in the preparation and storage of food might well form a part of the work of antenatal clinics. Other speakers also emphasized the importance of an adequate supply of vitamins during pregnancy. The incidence of puerperal pyrexia seems to be diminished by these means.

Maiden Castle, Dorchester: Excavations in 1937

EXCAVATIONS have now been resumed at Maiden Castle, Dorchester, under the direction of Dr. R. E. Mortimer Wheeler and Colonel C. D. Drew on behalf of the Society of Antiquaries and the Dorset Natural History and Archaeological Society (*The Times*, July 26). Three areas are to be explored in the coming season. At the eastern entrance, the unexpected discoveries made last autumn towards the close of last season's work will be further examined. These earlier fortifications, partly of masonry and dating from the third century B.C., which were found beneath the earthworks screening the entrance, include two outer gateways, which with the inner gateway constitute a complex plan hitherto unknown in prehistoric fortifications. Outside these are areas in which iron was smelted and burials took place. The latter should afford further evidence of the physical characters of the inhabitants, who according to the skeletons found last year were of a small build. Within the fort, investigations will be directed firstly to the Neolithic trenches found last year near the temple, which may have been part of the inner defensive system of the Neolithic partial occupation of c. 2000 B.C.; and secondly to the original western entrance, which was found in December last, but was not then explored. This last is marked by a gap in the rampart, which shows the original western limit of the castle, and should reveal the plan of the earliest gateway known. The first important discovery of the season is that of approach roads diverging in a north-easterly and south-easterly direction, which were superseded and abandoned in the first century B.C. and are thus among the earliest metalled roads known in Britain.

Evidence of Early Man at Bethlehem

To the antiquities from Tell Duweir on view at the Welloome Research Institution (see *NATURE*, July 17, p. 99) have been added, since the opening of the exhibition, finds from the Bethlehem Bone Beds, which are being excavated by the Welloome Marston Archaeological Research Expedition to the Near East. The work of investigation is being carried out by Miss D. Bate and Miss E. Gardner. The great pit, from the clays of which these finds are derived, appears to be a swallow hole. Rock has been reached on two sides, while on the third side what appears to be only a thin sheet of sloping deposits remains; but until bottom has been reached the exact form cannot be determined. There are indications that the cavity may fork as deposits are followed further. Among the animal remains found in 1937, the most

striking is the hinder part of the carapace of a gigantic tortoise, together with some detached plates and a bone of the same species. By way of contrast is the fossilized bone of a diminutive species of tortoise. There are also shown part of the tooth of an elephant—the first identification of an elephant in Palestine was from this site—the upper cheek-teeth of a rhinoceros and evidence of a very small form of horse, new to the fauna of Bethlehem. Although there has not yet been opportunity to identify the species with certainty, the indications point to a probably Lower Pleistocene horizon, or even possibly Pliocene. With the animal remains are shown flints selected from a larger number which were found in the bone beds and associated with the fossil fauna. Of these, one is apparently a core, while the others are of characteristic Eolithic or pre-Paleolithic forms. Both the character of the flaking and the forms would seem to place their human origin beyond question. Their association with the animal remains in a definite geological horizon constitutes them the earliest evidence of man's existence yet discovered in Palestine. The exhibition will close on August 7.

"Caves and Caving"

THE British Speleological Association, which met for its second annual conference at Bristol on July 23-26, may now be regarded as fully established. It has acquired Cragdale House, Settle, Yorks, for its headquarters—a 'shilling fund' to raise £500 has been initiated for its equipment by the women members—and it has issued the first number of a publication under the title "Caves and Caving" (1s., annual subscription 4s. 6d.), in which speleological studies will be treated scientifically, but in popular form. The first issue opens with Sir Arthur Keith's presidential address "History from Caves", delivered at Buxton last year, fronted by an excellent portrait of the author; Prof. L. S. Palmer follows with an account of the objects of the Association and its work up to the present, the latest undertaking to which he refers being the systematic study of the aquatic fauna to be found in cave streams; Mr. E. Simpson reviews the life-work in speleology of the veteran, M. E. A. Martel, honorary member of the British Speleological Association, and honorary president of the Spéléo Club de France at its foundation in 1930. Mr. A. Leslie Armstrong counsels caution in "Cave Exploration as a Science"; and Dr. Franco Anelli gives an account of the recent descent into La Preta Cavern in the Lessini Mountains of the Veronese, Italy, the deepest known cave in the world, when a depth of 637 metres (approximately 2,090 ft.) was reached. At the recent field meeting of the British Speleological Association at Gaping Ghyll Hole, Ingleborough, Yorks, 356 descents were made and half a mile of new passages were explored. This is Britain's largest cave. The history of its exploration is reviewed by Mr. E. Simpson in a contribution, to be continued. Among other articles is a first instalment of the extremely valuable record of cave finds, arranged under caves, which is being compiled through inquiry by Dr. Wilfrid Jackson.

It will, when complete, show the present location, museum or other, of all animal remains and artefacts of archaeological interest found in British caves, so far as can be ascertained.

New Penguin-breeding Record at Edinburgh

THE Scottish National Zoological Park at Edinburgh has long been famous for its penguins—not only for their number and variety and fine condition but also for the manner in which they have bred there. The king penguin bred first in the Park eighteen years ago, and since that time fifteen king penguin chicks have been bred and reared. The ringed penguin and the rockhopper penguin both bred in the Park two years ago. These were the first occasions on which these three species have bred in Britain, and probably the first time they have bred in captivity anywhere. The latest achievement of this kind is the breeding of the gentoo penguin. The gentoo penguin comes next in size to the king penguin. While the king penguin makes no nest but holds its single egg on its feet during incubation, and the rockhopper penguin and ringed penguin make a rough nest of a heap of pebbles, the gentoo penguin prefers something softer, and collects dead grass, twigs and small sticks which it shapes into a symmetrical nest. It was nearly two months after the beginning of the nest building that the first egg was laid, and a second egg was laid five days after the first. Both parents shared in the work of incubation, and took their turns fairly regularly. The first egg hatched after an incubation period of five weeks and four days, but the second was infertile. The chick has a nestling coat of pale grey on the back and white underneath, and it was observed to feed on the day it hatched. It feeds, as do all 'baby' penguins, by taking partially digested fish from the throat of the parent bird.

Acquisitions at the British Museum (Natural History)

MR. J. L. CHAWORTH-MUSTERS has presented to the Department of Zoology 82 birds belonging to 31 species, and a few field mice, which he collected in the High Atlas Mountains, above Marakesh, in the early part of the year. Included among the birds are examples of the rare crimson-winged finch, an alpine accentor, and local forms of the dipper and shore lark. The Entomological Department has received a welcome gift in the letter-book of Dru Drury, a famous collector and describer of insects (1725-1803). He was a goldsmith living in London who had correspondents in Asia, Africa, America, and Australia. This book contains copies, in his own hand, of letters written by him to his friends, his collectors, and his business connexions during the years 1761-1780, and gives a valuable insight into entomological proceedings during that period. Accompanying this volume, and similarly presented by Mr. Charles Dru Drury, are a copy of the auctioneer's catalogue of Dru Drury's collection (1801), and a small collection of letters addressed to him by Carl Linné the younger, by A. R. Lewin (from Australia), and by other well-known contemporary naturalists.

Accessions in the Department of Geology include a collection of nearly 200 fossil fruits and seeds from the Cromer forest bed, all described and figured by Mrs. E. M. Reid and her late husband Dr. Clement Reid, and now generously presented by Mrs. Reid. The Trustees approved the purchase for the Department of Minerals of a nugget of well-crystallized iridosmine (osmaridium), weighing nearly an ounce, from Adamsfield near the source of the Derwent in Tasmania. There is a larger nugget already in the collection weighing nearly two ounces and reputed to be the second largest nugget of pure iridosmine, but it is less well crystallized than the specimen now acquired. Other important purchases are a slice weighing 1,387 grammes of a rare type of meteorite—a pallasite—from Springwater, Saskatchewan, a fine aurichalcite from Utah, and a fine group of laumontite and a large crystal of adularia from northern Italy.

Televisor, Telegraphy, Telephone

THE word 'Televisor' was coined by Mr. J. L. Baird in 1925 to describe apparatus for television and was registered by him as a trade mark. On account, however, of the general adoption of the word in the United States and elsewhere to denote any kind of television apparatus, Baird Television, Ltd., has decided to abandon its registration as a trade mark, so that in future there will be no restriction upon the use of the word in connexion with television. 'Televisor' may thus be used in future as freely as 'telegraph' and 'telephone'. The word telegraph was first applied by Chappe in France, in 1792, to his invention of the semaphore system of transmitting messages to a distance; and the word telephone was used by Sudré in 1828 for a system of signalling by musical sounds. It was employed in 1844 to describe a powerful wind instrument to convey signals at sea during foggy weather. Philipp Reis, in 1861, called his ingenious instrument a telephone, so that he may be regarded as the inventor of the name of the modern instrument. Alexander Graham Bell adopted the word in 1876 for his "Electrical Speaking Telephone".

The Earl's Court Exhibition Centre

THE new Earl's Court Exhibition building, erected on the site of its predecessor, is approaching completion. It will be the largest permanent exhibition and sports centre in the British Isles. The site covers approximately twenty acres, the new buildings enclosing nine acres. The main arena is unique, as it is the largest concrete building in the country. There are no less than six electric railway tracks running underneath the site of this exhibition. These tracks were covered in by tunnels or bridged without interrupting the railway services. The main hall itself is 250 feet by 350 feet without columns, and has seating accommodation for about 25,000 people. A swimming pool having a capacity of 2½ million gallons of water is provided. An account is given in the *Electrical Times* of July 1 of the problems connected with the heating and lighting of the exhibition. Complete designs and estimates were

got out for all reasonable methods of doing this. The first step taken was to prepare designs and costs for a complete generating power station for the Exhibition and alternatively to use boiler-house plant for heating purposes. This was compared with possible tariffs obtained from the Fulham Power Station for an electric service for lighting power and complete heating of the building by electric thermal storage. The estimates were considered by the Company and its consultants, the conclusion being that electricity for all purposes was the best scheme. The Fulham Borough Council has undertaken to carry out the complete installation of all the electrical plant and services required up to the point of low-tension distribution together with the electric thermal storage plant, and the work is now on the point of completion. A permanent form of fire-fighting equipment is installed at every substation. The heating of the whole of the building is carried out by an electric thermal storage hot water plant which is much the largest plant of this kind in the British Isles.

History of Alchemy

THERE are welcome signs of an awakening interest in the history of science, the study of which has until recently received surprisingly little recognition among the increasing body of scientific workers in Great Britain. The appearance last year of *Annals of Science*, a quarterly journal devoted to the history of post-Renaissance science in general, has been quickly followed by another publication entitled *Ambix*, which is to deal with the specialized study of alchemy and early chemistry. *Ambix* is, indeed, the official journal of the newly founded Society for the Study of Alchemy and Early Chemistry. The first issue is dated May 1937; the second number will appear in November 1937; and thereafter it will be published as a quarterly. At first sight, the subject may appear too restricted to afford material for a quarterly periodical, but this impression is corrected by supplementary glances at Sir Robert Mond's introduction and the later contents of this issue. "Alchemy," writes Sir Robert, "records not only Man's groping for the truth and for the enrichment of his experiences, but at the same time the widening of the Human Mind and the accompanying evolution of thought."

ANOTHER point of view is presented by Prof. J. Ruska in his contribution on "Methods of Research in the History of Chemistry". Here he states that "we continually need new texts, we need summaries of contents, translations and commentaries . . . we need also the application of the keenest critical methods." *Ambix* has already begun to supply material of this kind. Thus, Prof. J. R. Partington contributes a fully documented article entitled "Albertus Magnus on Alchemy"; Dr. F. Sherwood Taylor, the editor, writes upon "The Origins of Greek Alchemy"; Mr. Gerard Heym opens a useful "Introduction to the Bibliography of Alchemy", and also discusses the "*Aurea Catena Homeri*". There are,

in addition, a report of a discussion upon chemical and alchemical symbolism; a translation of "The Visions of Zosimos", by Dr. Taylor; and reviews of four recent books, including notably Prof. Partington's "Origins and Development of Applied Chemistry" and Prof. J. Read's "Prelude to Chemistry". The nature of these two works, differing so widely in scope and treatment, conveys some idea of the ambit of *Ambix*.

Public Health in British India during 1934

THE annual report of the Public Health Commissioner with the Government of India (vol. 1), recently issued, surveys the vital statistics, public health and public health services of British India for the year 1934 (Government of India Press, New Delhi, 1936. Rs. 6 As. 2, or 10s.). The mid-year population is estimated to be 275,753,570, the births were 9,288,897, a rate per 1,000 of 34, and the deaths numbered 6,856,244, a rate per 1,000 of 25. The infant mortality per 1,000 live births was 187. Of the causes of death, malaria heads the list with 1,319,026 deaths, and this figure does not include the mortality caused indirectly by malaria. Deaths from respiratory diseases numbered 488,018, those from dysentery and diarrhoea 285,110 and from cholera 199,708. Smallpox, with 83,928 deaths, caused a greater mortality than plague, with 80,181 deaths. At the Research Institute, Kasauli, a number of cases of snake-bite have been treated with anti-venomous serum with a high percentage of recoveries—25 out of 29 cases of cobra bite, and 12 out of 13 cases of bite by Russell's viper. Lieut.-Colonel Jolly, the Commissioner, believes that the intensive public health propaganda carried out during the last ten or twelve years is beginning to bear fruit, and that interest is increasing in such matters as rural reconstruction, nutrition, child welfare and the prevention of epidemics.

Examinations in the United States

EXAMINATION, as a teacher's tool, has undergone remarkable modification in the past sixteen years in the United States. The search for an instrument of precision for the use of teachers in examining their pupils has engaged the ingenuity of a host of investigators, and the resultant devices, the true-false, the completion, the matching, the multiple-choice, the one-word, the problem and other objective-type tests have, to a large extent, supplanted the essay test. The United States Office of Education has recently issued a report (Bulletin 9/1936, Washington: Supt. of Documents. 10 cents) on testing practices of secondary school teachers of 1,600 schools, as described by themselves. It appears that, when constructing tests, about seventy-four per cent of them make use principally of the objective type, only sixteen per cent rely chiefly on the essay test and ten per cent make equal use of both. The report shows that the new style of tests is popular with teachers. Their simplicity appeals to them. But it is clear that their employment calls for watchful control. A principal advantage claimed for them—that a large

number of items can be answered in a short time and the subject-matter can thus be the more thoroughly sampled—has been unrealized in many cases through not using a sufficient number of questions. Of intelligence tests, the report says that few teachers really use the results.

The Swiss Earthquake Service

THE Swiss Seismological Commission, afterwards the Swiss Earthquake Service, is the oldest committee engaged in the study of earthquakes. For its foundation in 1878, we are indebted to the veteran geologist, Prof. Albert Heim. Two years later, it was followed by the British Association Committee on earthquakes in Japan, which, on Prof. Milne's return to Great Britain in 1895, enlarged its scope as the Seismological Committee. In 1883, shortly after the destructive Iachian earthquake of July 28, a geodynamic section was added to the Central Meteorological Office at Rome, which still carries on its useful work of studying Italian and other earthquakes; and, in 1892, the Imperial Earthquake Investigation Committee began its similar, but more extensive, work in Japan. The Swiss Committee, under the direction of Dr. E. Wanner, has recently issued its *Jahresbericht* for 1935, containing three valuable tables, the first on earthquakes sensible in Switzerland, twenty-seven in number, none of which reached destructive intensity; the second, of eighty earthquakes with origins as a rule less than three hundred miles distant; and the third, of a hundred and fifty earthquakes recorded at the five Swiss stations (Zurich, Chur, Neuchâtel, Basel and Sion), the distances of the origins being not less than six hundred miles.

Discussion on Lubrication and Lubricants

THE Council of the Institution of Mechanical Engineers, with the co-operation of other societies and institutions, has decided to hold a general discussion on lubrication and lubricants on October 13-15, when a series of some 140 papers from leading authorities throughout the world will be presented. The opportunity will be taken to review the present state of knowledge by means of a general discussion among those especially interested and qualified to discuss the major problems of the subject, with objects such as to endeavour to establish a correlation between theory and practice and to show how bearing design can be applied, to relate academic research with trade practice, to obtain current views upon bearing metals, and to review the significance of laboratory tests, including wear and friction tests. An exhibition will be held at the Science Museum, South Kensington, to illustrate the subjects under discussion, and will be devoted to lubricants, bearings and bearing materials, as well as to testing and other apparatus. The exhibition will be open for a fortnight from October 13. Support for the discussion has been given by twenty-nine British societies and technical institutions and by ten over-seas societies and technical bodies. The complete proceedings will be issued as a bound volume. Advance copies of the papers will be available for use at the meetings.

Application forms for tickets of admission and for copies of papers, and further information about the discussion may be obtained from the Secretary, Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1.

A Naked-eye Group of Sunspots

A *very* large group of sunspots, that is likely to develop into the largest group so far recorded during the present eleven-year cycle, came into view at the sun's east limb on July 22 in latitude 31° N. The date of central meridian passage is July 28.5; on August 4, the group will reach the sun's west limb. The group comprises a large leader spot and a follower of composite structure; these, with companion spots, covered no less than 2,000 millionths of the sun's hemisphere on July 24. On July 26 (the date of this report) the two chief component spots could be distinguished separately with the naked eye.

The Night Sky in August

THE moon is new on August 6 at 12.6^h and full on August 22^h at 0.8^h U.T. Conjunction with the planet Venus occurs on August 3 at 9^h, and from the northern part of England and in Scotland an occultation can be seen (see *NATURE*, July 17, p. 103). On August 18 at 23^h, there is a conjunction with Jupiter, and on August 24 at 20^h a conjunction with Saturn. On August 30, the moon occults the 5th magnitude star, α Tauri, the re-appearance at Greenwich taking place at 3^h 20^m at position angle 314° from the moon's north point. From sunset until sunrise during August, four bright planets are visible. Mars sets before midnight; Jupiter is on the meridian at 21^h in the middle of the month, followed by Saturn at 2^h; whilst Venus rises at about 1^h and is a brilliant object in the early morning skies, passing between Procyon and Castor and Pollux towards the end of the month. Uranus is nearly stationary in Aries and may be picked out from the background of stars of similar magnitude (about 6^m) with the help of the map given on p. 57 of the B.A.A. Handbook. At about 21^h the constellations on the meridian offer almost unlimited scope for interesting 'sweeps', which should include double stars such as α Herculis, θ Serpentis, β Cygni, γ Delphini and δ Cephei. The latter star is a notable short-period variable giving its name to a class of variable which, recognisable in the nearer extra-galactic nebulae, enables the distances of these remote systems to be determined. Of the nebulae and star clusters to be viewed with binoculars or a small telescope, the 'ring' nebula in Lyra, the 'dumb-bell' nebula in Vulpecula and the star cluster in Hercules should be easily located by means of a star atlas. The general outline of the Milky Way may also be studied with binoculars, noting the bifurcation near the bright star, Deneb, and the star clouds near the southern horizon. It may be recalled that towards a point at R.A. 18^{h} 4^m: Dec. $+31^{\circ}$ the solar system is moving into space with a speed of 12 miles a second. Between August 10 and 12, in particular, the sky may be watched for meteors of the Perseid stream. An ephemeris for the comet

Grigg-Skjellerup is given on p. 32 of the B.A.A. Handbook and also one for the comet Encke, which may possibly be picked up before long on its return to perihelion due next December. The periodicity of this comet, only 3.3 years—the shortest known period for a comet—was first recognised by Encke in 1819.

Announcements

The Earl of Rothes has accepted the appointment of chairman of the governors of Faraday House Electrical Engineering College, in succession to the late Lord Castletown.

DR. L. J. SPENCER, formerly keeper of minerals in the British Museum, has been elected a corresponding member of the Société Géologique de Belgique.

PROF. L. J. WITTS, professor of medicine in the University of London and physician to St. Bartholomew's Hospital and Prof. G. E. Gask, emeritus professor of surgery in the University of London, have been appointed members of the Medical Research Council, in succession to Sir Thomas Lewis and Sir David P. D. Wilkie, who retire on September 30.

THE Trustees have appointed Dr. S. Ochoa of the University of Madrid as Ray Lankester investigator for 1937, and Dr. Ochoa began his researches at the Marine Biological Association's laboratory in Plymouth on July 1, his subject being the experimental relationship of structure to environment in fishes and other animals. This work is a continuation of previous researches at Madrid and Heidelberg on the same subject.

THE first International Congress of Medical Public Health Officers organised by the syndicate of French medical hygienists under the auspices of the Health Section of the League of Nations will be held in Paris on October 20–21 under the presidency of Prof. J. Pariset. Further information can be obtained from Voyages Duchemin-Exprinter, 26 Avenue de l'Opéra, Paris 16.

THE twenty-ninth Annual Autumn Meeting of the Institute of Metals will be held at Sheffield on September 6–9. On September 6, Dr. D. R. Pye, deputy director of scientific research, Air Ministry, will deliver the sixteenth Autumn Lecture entitled, "Metallurgy and the Aero Engine". Further information can be obtained from the Secretary, Institute of Metals, 36 Victoria Street, London, S.W.1.

THE fourteenth annual conference of the Association of Special Libraries and Information Bureaux (ASLIB) will be held at Gonville and Caius College, Cambridge, on September 24–27, under the presidency of Sir Harry Lindsay, director of the Imperial Institute, who will give an address on "The Interrelation between Science, Agriculture and Industry". Further information can be obtained from the General Secretary, ASLIB, 31, Museum Street, London, W.C.1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 200.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Some New Types of Pleochroic Haloes

EXAMINATION of a large number of biotite specimens from all parts of the world by my students and myself¹ has shown the existence of six distinct types of pleochroic haloes. Two of these, the common type due to uranium and the rarer thorium type, arise from parent radioactive elements of such long periods that α -rays are still being emitted and the darkening of the ring structure is still progressing in these haloes. The remaining four types appear to arise from parents of such short periods that all activity must have long since ceased. The first two types may be referred to as 'active' haloes and the last four as 'extinct' haloes.

To avoid premature implications as to their origin, the extinct types will be designated as *A*, *B*, *C* and *D*. The *A* type is similar to that described by Joly² as "emanation haloes". Types *B*, *C* and *D* are believed to be new. A photomicrograph of a *C* type halo is shown as an example in Fig. 1.

Fig. 1.

The *A* type has one ring, *B* has two rings, *C* three rings and *D* one ring. Certain subsidiary rings, mainly due to the actinium family, are occasionally found. The results of measurements of ring radii with the halo photometer are shown in the accompanying table.

Type	Ring radius in microns	Associated α -particle	Number in group
<i>A</i>	19-80	Po	62
<i>B</i>	24-49	RaC'	24
	20-00	Po	24
<i>C</i>	24-50	RaC'	23
	24-03	RaA	25
	19-85	Po	21
<i>D</i>	16-21	Ra	26

In the third column is shown the α -particle, the range of which agrees with the ring radius within the limit of experimental error and which appears to be the most probable parent of the halo ring in question. The fourth column shows the number of rings actually measured on the photometer records of a limited number of very good haloes mounted on slides and sorted out as to type by visual inspection.

It is to be noted that all six types of haloes may be accounted for by known radioactive elements, and that the ring radii appear to be constant in haloes contained in minerals of all geological ages.

The extinct haloes are fairly common, except type *D*, which is rather rare. All have been observed in more than one biotite specimen. Compound haloes are also found which are due to the superposition of two extinct types, notably *A* and *C*. Extinct haloes are often found arranged along irregular lines the course of which has little relation to the crystal directions. Often a distinct narrow channel is visible, which passes through the centres of the haloes and is sometimes surrounded by a faintly darkened tubulation the radius of which is that of the haloes.

It seems clear that an explanation of the mode of formation of these new types of haloes lies in hydrothermal action, but a detailed consideration is beyond the scope of this letter. A full account of these haloes and a discussion of the mechanism of their formation will be given shortly elsewhere.

G. H. HENDERSON.

Colchicine, 'Phytocarcinomata' and Plant Hormones

COLCHICINE has been shown to produce a bulbous hypertrophy of the root tips and coleoptile of wheat seedlings¹. In these swellings, the appearance of the mitotic figures closely resembles those found in certain organs of animals treated with colchicine, and also in malignant tumours of animals^{2,3}. In this respect, the action of colchicine appears to be similar to that of *B. tumefaciens*, which causes the 'phytocarcinomata'. On the other hand, A. P. Dustin⁴, Amoroso⁵ and Peyron *et al.*⁶ have claimed that colchicine inhibits the growth of malignant tumours in animals.

I have tested the effect of colchicine on the growth of tumours in plants by the following method. Seventy tomato plants (var. Kondyne red), grown in pots, were inoculated on the same day, with a virulent strain of *B. tumefaciens*, five inoculations being made on the main stem of each plant. The plants were then divided into five groups. One group was used as a control; colchicine was tested on another

group; and the other three groups were used for experiments that I shall mention later.

Colchicine in a 1:10,000 aqueous solution was introduced through a cut in the stem, by a method I have previously described¹. On the average, 2.5 mgm. of the substance was absorbed by each plant during the period March 18-May 14, 1937. The accompanying table shows that the effect of this treatment was an inhibition of the growth of the tumours in the inoculated plants.

The other three groups of plants were used in control experiments, designed to test the possibility that hormonal changes in plants influence the growth of plant tumours. An attempt was made to influence the plant hormones by the following three methods:

(1) I excluded light from the terminal buds of one group of plants by capping them with a black cloth², on the grounds that the influence of light on the elaboration and circulation of growth hormones in plants is well known.

(2) In another group I removed the flowers, because this also influences the elaboration and circulation of plant hormones.

(3) I administered palmitic acid to the last group of plants, because palmitic acid, administered to animals simultaneously with sex hormones, increases the effect of the hormones³. The substance was administered to the plants in two successive doses of 10 ml. of a 5:1,000 solution per plant, and the solution was poured directly on to the soil. The experiments were carried out in ordinary greenhouse conditions (the greenhouse was generously put at my disposal by Madame A. Fester, of Antwerp).

Number of plants	15	10	10	5	30
Treatment	Colchicine	Capped terminal buds	Flowers removed	Palmitic acid	Control
Average weight of tumours per plant	1.173 gm.	1.345 gm.	2.063 gm.	1.510 gm.	3.406 gm.
Average weight of one tumour	0.311 gm.	0.206 gm.	0.277 gm.	0.228 gm.	0.444 gm.
Average number of tumours per plant	5.53	6.50	7.50	6.00	6.85

The table shows that all these three types of treatment produced inhibition of the growth of the plant tumours, and it is therefore suggested that inhibition was produced by a hormonal alteration. The possibility therefore cannot be excluded that colchicine inhibits the growth of plant tumours in a similar way, namely, through the intervention of the plant hormones.

Interaction of Nuclear Particles

FOLLOWING the results of scattering experiments, the hypothesis is now generally favoured¹ that the interaction forces in nuclei do not depend on the charge of the particles concerned. Then the general interaction potential for two particles 1 and 2, either of which may be a proton or a neutron, can be expressed as:

$$U_{12} = [W + \frac{1}{2}B(1 + (\sigma_1\sigma_2)) - \frac{1}{2}H(1 + (\tau_1\tau_2)) - \frac{1}{2}M(1 + (\sigma_1\sigma_2))(1 + (\tau_1\tau_2))]J(r_{12}) \quad (1)$$

Here σ_i is the spin vector of the particle i and τ_i the formally analogous "isotopic spin vector"²; τ_i has the value $+1$, if i is a proton, and -1 , if i is a neutron; W , B , H and M are four constants. From (1) we obtain $(W + B + H + M)J(r)$ as the potential in the ground state of the deuteron. If $J(r)$ is correspondingly normalized we may put:

$$W + B + H + M = 1 \quad (2)$$

The value of the energy of the singlet state, as derived from scattering experiments, is then accounted for very closely if we put:

$$W - B - H + M = \frac{1}{2} \quad (3)$$

Other relations between the four constants may be obtained from the consideration of heavy nuclei. As Breit and Feenberg³ first showed, the fact that heavy nuclei with extremely large binding energies do not exist is explained if we put:

$$a_1 = 4W + 2B - 2H - M < 0 \quad (i)$$

Further, since heavy nuclei of zero charge are experimentally unknown, we must have:

$$a_2 = 2W + B - 2H - M < 0 \quad (ii)$$

Further considerations by Volz⁴ led him to conclude that a_1 is very nearly zero (which is in agreement with the results of Inglis⁵), and also that a_2 is very nearly equal to 0. Taking $a_1 = a_2 = 0$, the four constants were then completely determined by Volz.

An additional requirement has hitherto apparently been overlooked: all known nuclei show a very large degree of spin-neutralization. Even in the heaviest nuclei, the total spin never exceeds about $10(h/4\pi)$. Heavy nuclei, in which the spin moments

of practically all the particles are parallel, must certainly be unstable. This leads to another condition, namely,

$$a_3 = 2W + 2B - H - M < 0 \quad (iii)$$

This inequality can immediately be deduced by analogy with (ii). One has only to note that (i) is invariant if σ , B and τ , $-H$ are interchanged.

Condition (iii) is not satisfied by the values of the four constants derived by Volz. The assumptions $a_1 = a_2 = a_3 = 0$ lead to equal energies for the triplet and the singlet states of the deuteron, in definite disagreement with experiment. One can satisfy all three conditions (i-iii) only by taking $a_2 < -\frac{1}{2}$. The limiting value $-\frac{1}{2}$ is, however, outside the limits for a_2 inferred by Volz. A negative value for a_1 would not give better agreement.

Note added in proof.

The manuscript of this note was sent to Dr. Volz, who kindly pointed out that the value $a_2 = -\frac{1}{2}$ may be considered as just within the limits of his

estimate. Dr. Volz, however, agrees that the values of the force constants calculated under the assumption $a_1 = a_2 = 0$ are shown by the above considerations to be improbable; the choice $a_1 = a_2 = 0$ should be more accurate.

Infra-red Spectrum and Molecular Structure of Diketopiperazine and Tetramethyldiketopiperazine

SANBORN¹ has concluded from her work on the chemical properties of glycine anhydride (diketopiperazine), that the molecule exists only in the enol-form (I). In view of the importance of the diketopiperazine configuration for the knowledge of the structure of the proteins, it seemed not without interest to look for further means of investigating the molecular structure of this substance. A very suitable method is the analysis of the infra-red spectrum. The absorption bands of diketopiperazine and its tetramethyl derivative were therefore observed with a quartz spectrometer in the region 2.8–3.6 μ . The effective slit-width was 0.02 μ . Each substance was deposited from a suspension in alcohol or ether, respectively, as a crystalline layer on the quartz window of an absorption cell. Following a suggestion of Dr. W. T. Astbury, the cell was then dried *in vacuo* over phosphorus pentoxide for 38 hours, so as to eliminate all traces of water which might have been adsorbed on the surface of the crystals. The cell was kept dry with phosphorus pentoxide throughout the course of the experiments.

Fig. 1.

The results are given in the accompanying table. The accuracy of the wave-length measurements is $\pm 0.003 \mu$.

ABSORPTION BANDS OF DIKETOPIPERAZINE AND TETRAMETHYLDI-KETOPIPERAZINE

Diketopiperazine (λ in μ)	Tetramethyl- diketopp. (λ in μ)	Assignment of bands to vibra- tions of molecular groups
2.928 } 2.953 }	2.964 } 2.983 }	Valence vibration of C=O groups, first overtone.
3.008	3.013	Valence vibration of N-H groups, fundamental.
3.478 } 3.525 }	3.490 } 3.538 } 3.569 }	Valence vibrations of -CH ₃ (column 1) and -CH ₂ (column 2) groups, fundamental.

The assignment of the bands to the molecular groups given in the table may be understood by

reference to the formulae, of which I shows the enol-form and II the keto-form of diketopiperazine. The presence of an O—H linkage, required by the former structure, would give a band in the region 2.87–2.97 μ , and —CH vibrations at 3.20–3.80 μ should also appear. (If the O—H group were linked to a C—C instead of a C=O valence, as has been suggested, a band at 3.03 μ would appear instead of that at 2.87–2.97 μ .) With the carefully dried specimen, however, no trace could be found of either the —CH vibrations or of a band at 3.03 μ , so that the bands at 2.928–2.953 μ cannot be ascribed to an O—H vibration associated with the enol-form. They are accordingly assigned to the first overtones of the C=O group, which is consistent with the keto-form of the compound. Additional evidence for this form is the presence of —CH bands between 3.4 μ and 3.6 μ , which shows that the diketopiperazine molecule cannot possess any double bonds between carbon atoms. Furthermore, the similarity of the spectrum of the tetramethyl derivative (where no possibility of a keto-enol tautomerism exists) with the spectrum of diketopiperazine confirms the conclusion that in the crystalline state the diketopiperazine occurs in the keto-form (II), free from mixture with the enol-form. It should be remarked, however, that the observations do not preclude the possibility that a certain amount of each substance exists in the lactim-form, in which the hydrogen is linked with the C=O groups instead of with the nitrogen atoms. The result of this transformation is a double bond between the nitrogen atoms and the carbon of the C(OH) groups. It is clear, however, from the occurrence of the NH bands, that the diketopiperazine and the tetramethyl derivative cannot be wholly in this form. A full account of the experiments and a detailed interpretation of the observed bands will be published elsewhere.

I am very much indebted to Prof. A. C. Chibnall and Dr. W. T. Astbury for providing me with the diketopiperazine and the tetramethyldiketopiperazine.

Radioactive Isotopes of Element 43

PROF. E. O. LAWRENCE, of the University of California, gave us a plate of molybdenum which had been irradiated with deuterons in the Berkeley cyclotron. The plate showed a strong radioactivity due to more than one body. The half-value periods are of the order of magnitude of some months. A chemical investigation of the activity ruled out any radioactive isotopes of zirconium, niobium, molybdenum or ruthenium, and shows most probably that the activity is due to isotopes of atomic number 43 (masurium of I. and W. Noddack).

Since the chemical properties of this element are practically unknown, we investigated the activity in order to collect some information on the chemistry of 43. This element bears the closest resemblance to rhenium, and shows the same reactions as rhenium with sulphuretted hydrogen, nitron, etc., but it can be separated from rhenium by the method used by Geilmann and Weibke¹ for the separation of molybdenum and rhenium.

We wish to express our thanks to the Radiation Laboratory of the University of California for the gift of molybdenum. A more detailed account will be published in the *Rend. Lincei*.

Optical Rotatory Power of Turbid Solutions in an Electric Field

IN a previous note in this journal¹, A. McLean and I published the results of some experiments on the rotation of the plane of polarization of organic compounds dissolved in various solvents under the action of an electric field. These measurements were continued, and the results published in the *Philosophical Magazine*² by J. Kunz and P. H. Babcock.

For some solutions the results could be repeated, but for other solutions the curves obtained were very complicated and could not be repeated, so that the explanation of the phenomenon given became doubtful. These measurements were continued, and we found that the solution of methylester in benzene showed a slight turbidity, due probably to a suspension of naphthalic anhydride; indeed the carefully filtered solution gave no effect, even under the action of alternating fields so high as 15,000 volts per centimetre. Therefore, either some type of compensation is present in this particular solution (such as opposite effects on solvent and ester), or the magnitude of rotation does not depend so much upon the electrical structure as was first assumed. As in the present experiment, the expected effect was not observed, the dipole induced in the given fields may be too small.

When it was found that the rotation was due to a suspension, experiments were carried out using finely grounded calcite, quartz, iron oxide (Fe_2O_3), china clay, sodium chloride, etc., all of which gave an effect. The calcite suspension in benzene was one of particular interest, since it gave rotations from zero to 15° ; in some cases a maximum rotation of 5° was observed at about 3,000 volts per centimetre; then the rotation decreased with increasing fields, reached a minimum and began to increase again. When the field decreased, the curve was either above or below the branch obtained by increasing fields. These features depended upon the platinum electrodes in the polarimeter tube, which were too flexible and were moved upon application of the higher voltages. The difference in the two paths is due to settling or to mixing. The tube was reconstructed by supporting the electrodes in three places, and then the rotation reached a constant value at comparatively low fields.

The optical activity of suspensions is well known; it has received much attention by French and German physicists and chemists³.

We have been investigating the effect described by Prof. Kunz and R. G. Labaw, first in conjunction with McLean, who, however, had to leave it to take up other work. Although the solutions were apparently quite clear and free from obvious particles, we were led to suspect in some cases that the result might be due to very minute crystals in suspension in the liquid; we have also heard from Prof. Kunz that he has come to the same conclusion. Very careful filtration through selected filter papers removes the optical activity. The conclusion is, then, that the effect is due to dichroism induced in the particles by the electric field, a phenomenon not entirely new, although its accurate quantitative investigation is beset by numerous difficulties.

Air-drag and the Equilibrium of Whirling Threads

IN the absence of all resistance to motion and assuming perfect flexibility, the differential equations of motion for a thread which carries a small spherical 'bob' and is whirled rapidly about a vertical axis by a horizontal arm give us an approximate solution for small amplitudes a plane sine wave—with reference to moving axes—leading to the well-known formula for plane vibrations¹. This approximate solution throws no light whatever on the stability of whirling threads as observed experimentally in air: these threads show 'necks' of appreciable amplitude in place of point nodes, the necks increasing in diameter the farther they are from the 'bob'. With sufficiently long threads and a large radius of the whirling arm, the sine outline disappears altogether.

I have recently found that if a term be introduced for air-drag—assumed proportional to the square of the linear velocity—the differential equations then admit of an approximate solution which not only gives the outline of the thread with surprising accuracy but also fully explains the limited stability of the system as described by Hall (*loc. cit.*).

For ease in experimental interpretation, the solution is best referred to moving rectangular axes, the vertical axis of whirl being the Z-axis. The form of solution is then:

$$x = R(1 + \frac{1}{2}\mu^2 x^2 + \frac{1}{24}\mu^4 x^4 \dots) \sin \beta x,$$

$$y = R\mu x(1 + \frac{1}{2}\mu^2 x^2 + \frac{1}{24}\mu^4 x^4 \dots) \cos \beta(1 + \frac{1}{2}R^2\beta^2)x;$$

where x is measured from the node of the lowest balloon, R is, effectively, the radius of the lowest balloon, determined by the radius of the whirling arm; β^2 is $m\omega^2/Mg$; m is thread mass per centimetre; ω is angular velocity of whirl; M is mass of 'bob'; g is gravitational constant; μ is $(\gamma/2\beta)(1 - \frac{1}{2}R^2\beta^2)R$; γ is $P\omega^2/Mg$; P is coefficient of air-drag per centimetre of vertical thread.

This solution gives the projection of the spiral thread on two perpendicular vertical planes. The x -values are conveniently referred to as the 'centrifugal wave', the y -values as the 'drag wave'. The period of the drag wave differs from that of the centrifugal wave by the small factor $\frac{1}{2}R^2\beta^2$, so that the positions of minimum amplitude do not coincide exactly with the nodes of the centrifugal wave. This point is clearly shown in photograph *b* of Hall's

note (*loc. cit.*). The accuracy of this solution appears to depend primarily on the magnitude of the expansion coefficient μ and is good, within this limitation, for very large values of the balloon amplitude: we are no longer tied to infinitely small amplitudes.

The value of μ is commonly so small that, with appropriate corrections which will be self-evident from the equations, if r is the radius of the first neck' and R is the radius of the first balloon, then

$$\frac{P}{m} = \frac{2r}{\pi R^2}$$

Measurements of this 'drag ratio' are now in progress, using a coincidence method involving a specially constructed prismatic instrument which eliminates the slight weight inseparable from these whirling systems.

Very fine threads are found to give larger values of the drag ratio than coarse ones in approximately the ratio of their diameters, as might be expected. There appears to be a slight decrease in the drag coefficient with increased whirling speed, which is possibly due to increased air swirl in the system or a departure from the square law.

I hope shortly to give elsewhere a full account of these measurements and the derivation of these equations.

Maintenance of the Pulsation in Cepheid Variables

THE oscillations induced in the principal modes of vibration of a star by a free oscillation in one of them, generally of the second order in the corresponding free amplitude, are unimportant unless magnified by resonance; so seems the evidence from Miss H. A. Kluyver's analysis¹. Hence, the motion in a Cepheid variable may be closely approximated to by the superposition of the oscillations of two modes of vibration, a free one and a forced one with half the period.

The damping constant of this composite motion is a weighted mean of the constants referring to the components, the weight factors being proportional to the energies of the separate oscillations. As, excepting exact commensurability, the ratio of these weight-factors is proportional to the square of the free amplitude, the dissipation of the energy of the pulsation depends on this amplitude.

As regards the damping constants of the components of the motion, it is to be remarked that each is the sum of positive and negative terms; the positive terms result from the dissipation of energy in the outer part of the star, hence probably are much larger for the mode of vibration corresponding to the forced oscillation; the negative terms, resulting from the generation of energy, probably are of the same order of magnitude in both cases. Hence the possibility arises that the damping constant belonging to the free oscillation is negative and that

belonging to the mode of vibration in forced oscillation is positive.

If the damping constants in actual stellar conditions have values corresponding to the possibility referred to, then the star may adjust its amplitude in such a way that the damping constant of the composite motion is zero: the pulsation may be maintained indefinitely. If a state of affairs is assumed in which the amplitude is very small, then the negative dissipation of energy of the free oscillation intensifies the motion, until the positive dissipation corresponding to the induced vibration restores the balance: a permanent state of pulsation has been reached.

Photo-decomposition of Aldehydes and Ketones

ALDEHYDES and ketones decompose in the gas phase in two main ways¹. Type I, predominant with short chain compounds, may be represented $RCOR' \rightarrow CO + (RR + RR' + R'R')$. Type II, predominant with long-chain compounds, involves a cracking of the long hydrocarbon chain in a position $\alpha - \beta$ to the carbonyl group, giving a lower carbonyl compound and an olefine.

We recently described² certain results obtained in a study of the photo-decompositions of such compounds in paraffinoid solution, in which circumstances both types of decomposition were found to occur, type I being subject to a marked temperature coefficient while type II is not.

These results have now been extended to other carbonyl compounds, and appear to be of general significance. Thus methyl ethyl and diethyl ketones in 10 per cent liquid paraffin solution show no appreciable photolysis at 20° C., but ready decomposition according to type I at 100°.

The products arising from the type I photolysis in all ketones studied in paraffinoid solution are modified in a very simple but profound way, for whereas in the gas phase a mixture of the three hydrocarbons RR , RR' and $R'R'$ together with an approximately equivalent volume of carbon monoxide is obtained, in solution the hydrocarbon products occupy more than double the volume of the carbon monoxide and consist only of the hydrogenated products of the alkyl radicals, RH and $R'H$. None of the RR' and $R'R'$ hydrocarbons, previously found in the gas phase can be detected. It is clear that the free radicals disengaged in the photolysis must mainly react with the molecules of the paraffin solvent rather than combine together, as they do in the vapour. That this is substantially true is shown by the fact that an unsaturation develops in the paraffin solvent which, on removal of the carbonyl compound by distillation *in vacuo*, can be titrated with bromine water, and is equivalent in amount to the unsaturation which would be expected from the volume of the products. This suggests a continuous interchange of hydrogen atoms between paraffinoid free radicals and paraffin molecules, until two such free radicals meeting react to give an olefine and a paraffin by disproportionation.

With methyl ethyl ketone, the ethane produced is in excess of the methane, and this and a deficiency of carbon monoxide with reference to the total hydrocarbon produced has been correlated with the

presence of acetaldehyde which we were able to estimate. These results suggest that the reaction

can occur in paraffinoid solution.

Aldehydes differ from ketones in that photo-decomposition according to type I occurs in solution at room temperatures, and further in that the gaseous products are for the most part the same as those in the gas phase. Thus in the case of acetaldehyde the main products are methane and carbon monoxide, with a slight excess of the former. Butaldehyde and isovaleraldehyde behave similarly giving practically equal volumes of carbon monoxide and saturated hydrocarbon. Both compounds decompose simultaneously according to types I and II, the proportion of each type being approximately the same as in the gas phase, and unchanged in the liquid between 20° and -80° C.

Since with aldehydes less than 2 per cent of hydrogen is found, and but little unsaturation is developed in the solvent, the mode of type I decomposition is strikingly differentiated from that of the ketones. Thus independent evidence is furnished for the conclusion at which we have already arrived*, that the hydrocarbon is produced from aldehydes mainly in one act, namely, $\text{RCHO} \rightarrow \text{RH} + \text{CO}$, whereas in ketones free radicals are first formed. This conclusion can also be shown to be in accord with the fact that, with ketones in solution, the type I decomposition is subject to a marked temperature coefficient, while with aldehydes it is not.

Elementary Cell and Space Group of Ethyl-chlorophyllide

CHLOROPHYLL itself prepared after Stoll¹ is amorphous, giving in X-ray photographs only one broad ring corresponding to a distance of 4.2 Å. However, by replacing the phytol group by the ethyl group, a crystallizable compound can be obtained. Ethyl-chlorophyllide was prepared from leaves of *Heracleum*, following also the method of Stoll. By evaporation from ethereal solutions small crystals, weighing about 2 γ, were obtained in the form of thin equilateral triangles. The crystal form was, as already remarked by Willstätter and Stoll¹, clearly trigonal hemiedric (symmetry class C_3).

X-ray diagrams with copper K α-rays were obtained by oscillation through various angles about the a -axis [1010] and about [1120], the a -axis being parallel to the side of the triangle.

The dimensions of the elementary cell are: $a = 8.90 \pm 0.02$ Å.; $c = 38.4 \pm 0.2$ Å. For the density, the value 1.11 as found for chlorophyll was taken. The number of molecules of $\text{C}_{31}\text{H}_{50}\text{ON}_2\text{Mg} \cdot \text{CO}_2\text{CH}_3 \cdot \text{CO}_2\text{C}_2\text{H}_5 \cdot \text{H}_2\text{O}$ (the crystals were most probably those of the α -component) contained in the

cell was thus found to be 2.7 or approximately 3 so the exact value of the density is 1.24.

The X-ray diagrams confirmed the presence of a threefold axis, with no symmetry plane through the c -axis or at right angles to this axis. So only the symmetry classes C_3 and C_3 are possible, the latter being improbable from the external form of the crystals. As only those reflections 000 l for which $l = 3n$ are found and, further, many of the reflections are inconsistent with a rhombohedral lattice, the space group will be one of the pair of enantiomorphic groups C_3^+ and C_3^- . In these space groups the centres of the molecules, that is, the magnesium atoms, will be arranged in spirals around the c -axis.

A discussion of the observed intensities in relation to the shape of the molecules will be given later. We intend to investigate also the compounds derived from ethyl-chlorophyllide by replacing the magnesium atom by other bivalent metals such as copper and zinc.

Oestrous Reactions, including Mating, Produced by Triphenyl Ethylene

DODDS and his co-workers have described a number of synthetic substances with oestrogenic activity.

We have found that 1.0 mgm. of triphenyl ethylene¹, dissolved in oil, produced full vaginal cornification when injected into ovariectomized mice. A dose of 10 mgm. injected in two doses on two successive days produced cornification lasting for some eight to nine weeks, and partial cornification was present for a further period. The injections also caused oestrous distention of the uterus. Ten ovariectomized mice injected with 10 mgm. of the substance were placed with potent males and five of these have mated, as judged by the finding of vaginal plugs; one of these animals mated twice, namely, 5 and 15 days after the injections.

Oestrous changes in the uterus and in the vulva and also mating have been induced in each of two hypophysectomized rabbits.

Although the oestrogenic activity of triphenyl ethylene, as estimated by vaginal cornification, is only about 1/10,000 that of oestrone, yet it can produce effects of remarkable duration, and its power to produce mating is also noteworthy.

The minimum amount of the substance necessary to produce vaginal cornification when given by mouth in solution of oil is approximately the same as when given subcutaneously. Larger doses given by mouth produce cornification lasting for about a week.

Neural Induction by Plant Tissues in the Ectoderm of the Gastrula of *Triton taeniatus*

To investigate the problem concerning the induction of plant tissues in the ectoderm of the gastrula, plant tissues rich in nuclear and plasmatic content were used, such as meristem, cambium, ovaries and others. Fragments of these tissues, living or dead, were implanted into the blastocoel of an early gastrula of *Triton*.

Four series of experiments were carried out. In the first series, fragments of oat root meristem were inserted either in the fresh condition or after subjection to short boiling in water. Thickenings were formed in the ectoderm at the points in contact with the implant. In the second series, pieces of growing shoots of potato shoots were used, fresh or boiled. Greater proliferation of the ectodermal cells in the region of contact took place. In the third series, ash cambium of the birch tree was grated and introduced immediately into the blastocoel of a growing gastrula. Clear instances of inductions of neural plate were obtained, the superficial and deep layers showing a definite differential effect. As might be expected, the cambial layer was the most effective. The reason for this may be that the more tender membranes of the cambium are more easily destroyed by grating. The fourth series forms the control, and shows that the cell membrane is an insurmountable obstacle for inducing substances. Plant subjects such as anthers or whole stamens were implanted with impaired cell membranes. In these cases no induction was obtained.

Our results contradict those of Holtfreter's work with plant material (1934, p. 348)¹, but they suggest an explanation of the negative results of his experiments. Holtfreter used plant objects containing much nutritive material (pieces of banana, dough of wheat flour, potato starch).

The unity of plant and animal tissues thus shown by this corroboration in the biochemical field. Menandt and Jacobi (1933)² extracted folliculin from palm seeds. This folliculin was identical with folliculin $C_{12}H_{22}O_2$. Skarzynski (1933)³ obtained a derivative of follicular hormone from flowers, whereas up to that time this substance had only been obtained from the urine of pregnant women and from the contents.

Neural Induction by Fragments of Dead Tissues of Organs of Amphibia and Mammalia in the Ectoderm of the Anuran Gastrula

In the springs of 1934 and 1935, experiments were carried out on the influence of pieces of dead tissue (killed organs of desiccation, boiling and treatment with alcohol) on the ectoderm of the gastrula of Anura. Experiments were carried out in which parts of organs of tadpoles and adult Mammalia were implanted into the blastocoel cavity of the gastrula.

Eggs of *Bufo viridis* proved to be the best test material, but eggs of *Rana esculenta* were also used. The results gave positive results. Pieces of the upper

lip of the blastopore were desiccated at 60°, others were boiled in water. Some were fixed in 95 per cent alcohol, and later resoftened.

Fragments of muscle, brain and liver were the most effective of all the organs of anuran tadpoles. Fragments of mammalian organs, especially of liver and of kidneys, showed the highest inductive capacity. Our results confirm the work of Holtfreter (1934)¹, who has shown that mammalian tissues are the most effective in inducing axial organs, and add weight to the view that neural induction is chemical in nature.

Distribution of the Biting-louse

THE biting-louse, *Heterodoxus longitarsus* (Piaget), is primarily a parasite of certain didelphian mammals (Macropodidae), but it has been found also upon non-didelphian hosts. It has been recorded from domestic dogs, a jackal, a coyote, *Oncifelis salinarum*, and a man; also from the passerine bird *Corone australis*. We have examined the original specimens of most of these records and, in addition, have a number of new records from the dog.

This straggling is of interest from two points of view. First, the parasite has become established upon one of these non-didelphian hosts, the domestic dog and is even the usual dog louse in some localities. Secondly, on this host it appears to have a geographical and local distribution. Of the conditions necessary for the establishment of a louse species on a host other than its 'phylogenetic' host nothing is known, but with the apparent opportunities for transference it is amazing that it has not occurred more often. The earliest date recorded for the occurrence of the parasite on a non-didelphian host is 1902, in Africa.

On examining the locality records, there seems to be a definite geographical distribution such that it occurs only in temperate and tropical areas, roughly confined between lat. 40° N. and lat. 40° S. Thus, we are informed that the parasite is not known from the U.S.S.R., or from Canada; and it does not appear to occur in Europe. The information, from the literature in our records, indicates that within the two parallels of latitude the distribution is localized.

We are indebted to a great number of workers for our data. Accounts of the distribution and of the diagnostic anatomy of the parasite are in preparation.

"The Handbook of British Birds"

As many ornithologists are already aware, a new edition of "A Practical Handbook of British Birds" has been for some time in preparation. We should be very grateful to any of your readers who would now send us notes of any omissions or errors in the original work, and of any unpublished observation

which would make the work more accurate and complete. Should secrecy in regard to locality be necessary, this will be rigidly respected.

Since the "Handbook" was completed twelve years ago, such a vast amount of matter relating to distribution, migration, breeding-habits and food has been published, both at home and abroad, that the revision made necessary is a very heavy task involving the rewriting of most of these sections.

Moreover, field characters, habitat, song and 'habits' generally, to which very little space was devoted in the original work, will be greatly expanded, and these new sections are being undertaken by Mr. B. W. Tucker (with Mr. Charles Oldham's kind approbation).

The new work will be very fully illustrated in colour, the aim being to show all the birds in so far as possible all their plumages. Such a series of illus-

trations is not now available to British ornithologists and it is hoped that this new feature will greatly enhance the usefulness of the work, especially observers in the field.

The original "Practical Handbook" will be in fact so much a new work that we consider an alteration of the title to "The Handbook of British Birds" justified.

As it is proposed to publish in five volumes six-monthly intervals, beginning next spring, we shall be glad to have now any notes relating to order Passeres. It would be a convenience if observations concerning breeding habits or food were sent direct to the Rev. F. C. R. Jourdain at Bellevue Road, Southbourne, and all other notes to me at Graciosa Pond Farm, Chobham, Surrey.

H. F. WITHERBY.

July 21.

Points from Foregoing Letters

THREE new types of pleochroic haloes have been found by Prof. G. H. Henderson in the course of an extended examination of biotite specimens. Apparently these are due to certain elements of the uranium family, and are of hydrothermal origin.

A table comparing the ability of colchicine to reduce the size of plant tumours (induced in tomato plants by *B. tumefaciens*) with the effect produced by palmitic acid, by removing the flowers, or covering the terminal buds, is given by L. Havas. The author infers that colchicine, like the other factors mentioned, inhibits the growth through the intervention of plant hormones.

Dr. N. Kemmer gives a condition that must be satisfied by nuclear force-constants in order to account for the fact that nuclei with very large spin do not exist. The force constants previously derived by Volz must be altered to fulfil this condition.

Dr. Lotte Kallner concludes, from infra-red absorption spectrum observations, that in the dry crystalline state the molecules of diketopiperazine and tetramethyldiketopiperazine exist in the keto-form free from mixture with the enol-form.

A radioactive element formed in molybdenum radiated with deuterons has been investigated by Perrier and Prof. E. Segrè. They attribute the radioactivity to isotopes of atomic number 43 (nasurium), and find that their reactions are similar to those of the element rhenium.

Further experiments by Dr. J. Kunz and others show that the rotation of the plane of polarization attributed by J. Kunz and P. H. Babcock to organic compounds dissolved in various solvents, under the influence of an electric field, is in reality due to the dichroism induced in suspended particles by the electric field, a phenomenon already known.

An approximate solution of the differential equations of motion of loaded, flexible threads whirling about a vertical axis and subject to air-drag has been developed by E. R. Goshawk. The solution accounts for the limited stability of such systems and is not materially affected by the amplitude of whirl. A simple method is indicated for measuring the air resistance to the motion of cylindrical threads—rough or smooth—at high whirling speeds.

Dr. J. Woltjer, jun., points out the possibility of the existence of a self-regulating mechanism which would maintain the pulsation of a star, depending on the superposition of the oscillations of two modes of vibration, a free and a forced one.

Two types of decomposition of the methyl-ethyl and diethyl ketones in 10 per cent liquid paraffin solution, are described by Prof. R. G. W. Norrish and C. H. Bamford. They find that solvent molecules react with the radicals liberated by the photolysis.

An X-ray investigation by Dr. J. A. A. Ketelaar and E. A. Hanson of the ethyl derivative of chlorophyll, said to be the first of the chlorophyll derivatives to be examined by the X-rays, indicates that molecules are arranged in spirals.

Three crystalline pigments belonging to the group of carotenoids have been obtained by Dr. G. W. and H. Zussman from extracts of chicken retina. One is purplish red (astaxanthin), another a golden orange xanthophyll, and the third a yellow or yellow-green hydrocarbon. None of these absorbs light in the region 600–700 mμ, and the authors suggest that the chicken, like the pigeon, may be unable to discriminate hue differences in this region.

Curves showing that the maximum sensitivity of photographic plates sensitized with dye-stuffs (thiosin and phloxine) corresponds with maximum absorption by these dyes when absorbed on films of silver bromide (but not with their maximum absorption when in solution) are submitted by Natanson.

Dr. J. Needham and H. Lehmann have investigated the inhibition of embryonic glycolysis by glyceraldehyde—it is due only to *D*-glyceraldehyde. They find that the inhibition is apparently incomplete in the presence of lactic acid formation from glyceraldehyde. This is brought about by its transformation to methylglyoxal, which is then converted to lactate by glyoxalase.

S. Paramasivan reports that the paintings of the temple of Vijayalaya Cholisvaram at Nartham, Pudukottah State (South India) have been examined in a technique which is a combination of fresco and tempera. Lime, carbon, yellow and red ochre, terre verte have been used as pigments.

Research Items

The Quinault Indians, Washington, U.S.A.

THE Indians who speak a Salish dialect lived in a region of the State of Washington, of which the Quinault River, with its valley, was the heart. In addition to the region drained by the river, they also occupied a district along the beach between a point near the mouth of the Raft River and a spot near the present site of the village of Pacific Beach, or the mouth of Joe Creek. In practice, their boundaries were not strictly defined, and the feeling of ownership or exclusive right to this territory was unheard of. The heights above the source of the river were more or less common hunting ground for several neighbouring tribes. The whole region was covered with a luxuriant growth of vegetation. In 1856, they ceded part of their territory to the Government, and since then have lived in the present Quinault Indian Reservation. Between 1925 and 1927 they were visited on three occasions by Mr. Ronald L. Olson under the auspices of the Department of Anthropology, University of Washington, for the purpose of studying the vanishing relics of their tribal culture, of which there has been no systematic description (*Univ. Washington Pub. in Anthropol.*, 6, 1). "Quinault" is a corruption of "kwi'nail", the name of the largest settlement situated at the site of the present village of Taholah. A list of thirty-eight village settlements which had existed along the course of the river was obtained, while some seventy-seven place-names were collected. An approximate estimate for the population at the beginning of the nineteenth century is eight hundred. Their most important economic activity was the taking of salmon, of which the great run began in March or April. During the run, the men virtually lived at the weir, the fish being passed to the women for dressing and curing. After the run, a variety of activities was open. Some might go to the mountains for hunting elk, bear and deer, others might go to the coast to gather clams, while for every household the winter's supply of bark, grass and roots for baskets and clothing had to be gathered.

Daylight Illumination for Clerical Workers

AN interesting investigation into the problem of the daylight illumination which ought to be provided for clerical workers has been described by L. H. McDermott ("Daylight Illumination Necessary for Clerical Work", Dept. Sci. and Indust. Res., Illumination Res. Tech. Paper No. 19. Pp. iv + 14 + 2 plates. London: H.M. Stationary Office, 1937. 6d. net). A mechanical method was devised to ascertain the value of daylight illumination below which workers will make use of artificial light. Briefly, the method employed consisted in photographing a micro-ammeter connected to a photo-electric cell, the motive force for working the camera being derived from the current in the lamp circuit when the subject first switched on the light. The photo-cell was exposed to daylight in a fixed position in one of the office windows, and the reading of the micro-ammeter thus bore a definite relation to the illumination at any particular desk. This relation was determined for each desk occupied by a subject under investi-

gation, and thus it was possible to calculate the daylight illumination at any desk at the moment when the worker made use of the desk light. The results of more than a thousand observations made in a study of seventeen typists are analysed and tabulated. The illuminating value at which the average subject needed artificial light was about 5 foot-candles. Individual subjects varied somewhat in their minimum requirements, but the conclusion that 5 foot-candles is the minimum daylight illumination requirement of the average typist appears to be justified. This result can be applied to determine the average lighting-up time at any season of the year for any given point in a room if the daylight factor for that point is known, and if data concerning the variation of outdoor illumination throughout the day at all times of the year are available. A table is given showing, for positions with various daylight factors, the periods for which natural illumination is sufficient for typists working at desks with specified daylight factors. The figures relate to a non-urban locality in the south of England.

Age and Stock of Blue Whales

THE corpora lutea of whales regress into corpora albicantia, but apparently never become entirely absorbed, so that the ovaries retain a record of the total number of ovulations during the life-history of any female. From material examined in the antarctic, and ovaries extracted and sent to London by whaling factories there, together with date of length, sexual condition, and ankylosis of vertebral epiphyses, Alec H. Laurie has deduced certain important conclusions regarding the antarctic Blue whales (*Discovery Reports*, 15, 223-284, 1937; Camb. Univ. Press, 9s. net). The onset of maturity corresponds with the accumulation of eleven corpora lutea in the ovaries, and a minimum body-length of 86 feet, which is attained at ten to eleven years of age. Breeding may take place every two years at best, and a possible average rate of once in two and a half years is suggested. The oldest females taken, probably about thirty years of age, showed no sign of diminishing fertility. The age distribution of the females points to a progressive fall-off in the rate of recruitment of the stock in recent years, so much so that the author considers it now to be insufficient to compensate for the slaughter of modern intensive whaling. Another suspicious fact bearing upon the same point, is the decrease which (contrary to the analysis made by Hjort, Lie and Rrud) is shown in the average length of females captured. From 82.86 feet in 1930-31, the average length has fallen to 78.99 feet in 1935-36, which means that on an average females are killed before they have even begun to reproduce, and in accordance with this the percentage of immature females captured has risen from 15.16 in 1930-31 to 41.67 in 1935-36. These conclusions point to a serious situation. It would appear that the stock of antarctic Blue whales is steadily being encroached upon, since the annual breeding rate is insufficient to cope with the annual destruction (see also p. 180).

A Pest of the Rhododendron

MR. G. FOX WILSON has directed the attention of gardeners to the appearance in Great Britain of a leaf-hopper, *Graphocephala coccinea*, upon the leaves of species of *Rhododendron* and *Kalmia* (*J. Roy. Hort. Soc.*, 62, Pt. 5, May 1937). The pest normally inhabits the eastern half of the United States. It seems to cause little direct damage to its host, but apparently allows bacteria or fungi to enter the plant tissue, and thus induces secondary infection. Applications of nicotine are recommended where it is necessary to control the activities of the pest.

Chemical Analyses of Rocks and Minerals

BULL. 878 of the Geological Survey of the United States is devoted to a record of analyses of rocks and minerals made in the Laboratory of the U.S. Geological Survey during the years 1914-36. It is supplementary to Bull. 591, which contains the 2,789 analyses made up to January 1, 1914. In the present compilation, for which R. C. Wells, the present chief chemist, is responsible, the details of 1,533 additional analyses are given, including 444 of igneous and crystalline rocks; 303 sedimentary rocks; 115 clays and soils; 156 ores and gangue materials and 515 minerals. Although many of the analyses have already been published, a considerable number have not hitherto been recorded. Moreover, those published are very widely scattered, and some of them would be impossible to find without a great expenditure of time. The Bulletin is therefore likely to be of great value to petrologists and mineralogists. No attempt is made to recalculate the average composition of the earth's crust, but Fersman's figures for the abundance of all the elements—based on the whole of the data available up to 1932—are reproduced from their relatively inaccessible Russian source. Attention is directed to Fersman's new term *clarks* to designate a unit for indicating the relative abundance of an element, either by weight or by number of atoms, in any particular type of rock or in the earth's crust, in honour of F. W. Clarke, who did so much for geochemistry, especially on the statistical side.

Size of Particles Responsible for Ferromagnetism

DIA- and para-magnetism can be explained almost entirely on the basis of the magnetic properties of single atoms; but the phenomena associated with ferromagnetism only appear in aggregates of atoms arranged in a certain manner. These aggregates, it is estimated, should be of ultra-microscopic dimensions. It is therefore to be expected that a study of the structure of aerosols of iron and nickel with the ultra-microscope should yield some information on the size of the elementary magnets of these ferromagnetic substances. Observations by this method are reported by D. Beischer and A. Winkel (*Naturwiss.*, 25, 420; 1937). The nickel and iron aerosols were produced by the thermal decomposition of nickel tetracarbonyl and iron pentacarbonyl, respectively, in nitrogen. Examination of the aerosols under the ultra-microscope showed that the particles were chain-like. This is unusual for this type of sol, which more often forms spherical aggregates, chain-like particles being formed only when some directive force is operative. It is suggested that the force in this case is magnetic. The view is supported by the fact that

the velocity of aggregation is considerably greater than is usual with aerosols, and that if the aggregation takes place at a temperature above the Curie point, no chain-like particles are observed, but aggregation results in the formation of spherical particles. Estimation of the size of the smallest particles of which the chains are composed from the widening of the Debye-Scherrer diagram gives results which are in agreement with the requirements of the Weiss-Heisenberg theory of ferromagnetism. Experiments are also described which indicate that the magnetism of the particles is spontaneous, and not induced by the earth's field.

Polymorphic Changes of the Alkaline-Earth Carbonates

AN interesting application of Hahn's emanation method of investigating changes of structure of solids has been made in the examination of the polymorphic changes of calcium and barium carbonates (K. E. Zimens, *Naturwiss.*, 25, 429; 1937). The curve of amount of emanation evolved against temperature indicates a transition in the case of calcium carbonate from the aragonite to the hexagonal calcite structure at about 500°. The change is monotropic. Barium carbonate shows an enantiotropic change at 800° from the rhombic to the hexagonal form. A further transformation at 982°, which has been reported in the literature, could not be detected.

Mud Fluid for Pressure Drilling Conditions

A HEAVY loaded mud should be used in conjunction with pressure drilling equipment when very high pressures are to be dealt with. Also, it may be convenient to use a mud of this description in circumstances where pressure could be controlled equally effectively either by back pressure or by a loaded mud fluid, for in the event of a formation being encountered where a higher pressure exists such pressure can be immediately controlled by increasing the back pressure applied at surface. Dr. J. T. Evans, in a paper presented to the Burma Branch of the Institution of Petroleum Technologists on May 4, pointed out that the preparation of loaded muds has two stages: mixing clay or shale with water to give an ordinary rotary mud, and afterwards mixing barytes with this mud until the desired weight is achieved. It is clear that the desired final characteristics of the mud must determine the type of shale or clay to be used, but the clay best suited for a loaded mud base is not necessarily that best suited for an ordinary mud, since if ordinary mud should become viscous at slightly higher weight it would involve heavy expenditure on barytes to produce the final loaded product. This factor and the properties of weight, stability, viscosity and reaction to chemicals used to reduce viscosity should all be taken into consideration when preparing a specification for loaded mud. Then again, conditions are materially altered when the mud is put into service. Pressure, temperature, etc., are liable to have some effect on the characteristics of the mud, and these factors must be borne in mind when assessing the usefulness of a given loaded mud. Finally, it is quite probable that the admixture of drilling mud with formations penetrated and the phenomenon of thixotropy, whereby alternating gel and sol conditions are produced, will alter the characteristics of the loaded fluid in service.

Science and the Conservation of Food*

AGENCIES AFFECTING FOODS

THERE are many agencies, biological, chemical and physical, which may affect foodstuffs, either by spoiling their appearance or rendering them unfit for consumption. Bacteria are most important among the biological factors, but yeasts and moulds, which may either aid or hinder preservation, have also to be considered; and then there are such animal pests as sugar- and cheese-mites, moths, rats and beetles, all of which may damage the raw material used in food manufacture, or attack the finished products.

Food products have also to be protected from heat, dampness, the oxygen of the air and sometimes from light as well. These last two factors, acting in association, produce the bleaching or discoloration which is sometimes seen in bottled fruit, when pieces of the fruit project beyond the syrup into the space at the top of the bottle. Then again, canned food must be protected from the action of acids and salts which might corrode the tin.

There are also substances contained in the foodstuffs themselves which may have a destructive action, namely, the enzymes. These are present in both vegetable and animal cells, but they can exist independently of them. One enzyme having an important bearing on food preservation in connexion with jam-making is pectase, which, if it is allowed to do so, will destroy the pectin which is responsible for the 'setting' property of jam. Jams, in fact, present a number of problems to the manufacturer, and the way he has been helped to solve these is a good example of the assistance which science has rendered to industry.

JAMS

Substances of importance for the keeping quality of jam are held in solution in the water it contains, for example, sugar, acids and salts. The osmotic pressure of these substances, the sugar in particular, can be responsible for protecting the jam from the growth of moulds, because, for germination, a mould spore must first absorb water. If the osmotic pressure of the jam is equal to or greater than that of any spore which falls upon it, either no water will pass from the jam to the spore or the spore will lose water and so dry up and eventually die, and in both these cases its further development will be arrested. The British Food Manufacturers' Research Association has actually determined the minimum percentage of solids necessary to bring about this condition.

There is, however, still a risk of moulds developing in a jam if the relative humidity of the atmosphere to which it is exposed is above 82 per cent.. Then the jam will absorb moisture and so its osmotic pressure becomes lower than that of the mould spores.

Another defect frequently arising in jams is crystallization or granulation of the sugar. In the jam-making process, sucrose is inverted by the boiling acid, and it is necessary that just the right degree

of inversion should take place if no crystallization is to occur. Thus, if the sugar is under-inverted too much sucrose is left and this crystallizes out. If, on the other hand, it is over-inverted, too much dextrose is formed and this crystallizes out. As fruits vary very much in the amount of acid they contain, the manufacturer must be able to discover the degree of inversion taking place, and modify his process accordingly.

The setting property of jam has already been mentioned, and it is important to remember that unless jam is properly set it cannot be transported and handled. It is therefore necessary to make use of the pectin naturally occurring in fruit cells. Pectin is a complex of different substances, and therefore its properties vary from one fruit to another; for this reason the setting properties of some fruit juices are superior to those of others, for example, gooseberry, red currant and apple are good, while strawberry is poor. Now, pectin must be protected from the naturally occurring enzyme, pectase, which destroys it. So long as the cell structure remains intact, the pectase does not attack the pectin, but in fruit which has become damaged by bruising, the pectase appears to get out of control, and in the case of raspberries all the pectin may disappear in twelve hours. In this fact lies the justification for manufacturers using "added fruit juice" or "pectin" in the making of jam.

Pectin may also lose its jellifying powers by the action of prolonged heat. It is therefore necessary to eliminate any over-heating in the manufacturing process, and this is not always easy when large quantities of liquid have to be dealt with.

MEAT PRODUCTS

The processes of jam-making are more familiar to the public than those of meat preservation. An important difference to bear in mind is that meat has no natural acids to assist the preservation process. Meat, if it is to be kept, must be protected from putrefactive bacteria, which though harmless in themselves feed upon animal and vegetable debris, gradually converting them into ammonia and carbon dioxide, etc.

Refrigeration deprives the bacteria of water which is necessary for their growth, the water in the meat tissues being converted into ice. The bacteria are not necessarily killed, but their development is inhibited. Some of the bacteria can grow at temperatures around freezing point, and for this reason chilled meat cannot be kept so long as meat which is frozen at temperatures well below freezing point. The growth of bacteria can also be restrained by certain concentrations of carbon dioxide in the air.

Although the spores of some bacteria are highly resistant to heat, it has been possible to use heat sterilization as a method for meat preservation. It is, of course, necessary for the manufacturer to know the combinations of time and temperature at which all spores likely to be present will be destroyed.

* Substance of a Friday evening discourse delivered at the Royal Institution on April 16, by Mr. T. Macara, director of research of the British Food Manufacturers' Research Association.

Allowance must be made, when the product is packed in a tin, for the penetration of heat to the deepest parts of the package; and the rate of penetration will vary considerably with the density of the contents, being much slower for meat than for a tin of fluid.

FOOD POISONING

A product canned by correct processes is one of the safest articles of diet it is possible to have, and many complaints made to manufacturers that their products have caused illness, have shown on investigation to have no justification. According to Prof. Tanner of Illinois (speaking at the Congress of Microbiology, 1936), in the past cannery and distributors have tried to avoid publicity by settling their claims out of court. Medical practitioners are often unfamiliar with the procedures necessary to establish definitely the causative factors in food poisoning. There is also much prejudice on the part of the public as well as ignorance of the great care generally taken in the manufacture of these products. It has been shown in Great Britain and the United States that by far the largest number of cases of food poisoning are caused by foods which have been prepared in the home or by products sold in a pre-cooked condition, but not sterilized.

TINPLATE CONTAINERS

A difficulty, still not completely solved, is that of producing in commercial quantities the perfect tinplate for the construction of a can, or tin stopper for a glass jar. Then also, the machinery necessary in making the can may break the tin coating and expose the base metal, iron. The iron thus exposed may be attacked by the salt present in meat and

vegetable products. An attempt has been made to produce a lacquer which when applied to the tin plate would prevent this action. Several difficulties have so far prevented the realization of this ideal.

PRESERVATION OF MEAT

The preservation of meat by means of salts has long been practised, but only recently have its scientific principles been studied. The production of colour as well as preservation from putrefaction is brought about by the use of saltpetre. Bacteria action converts the nitrate of the saltpetre into nitrite, which combines with hæmoglobin, and when the meat is boiled the latter is converted into nitro-hæmochromogen, which has the bright red colour characteristic of properly cured silverside. The micrococci responsible for this action can grow in media containing as much as 20 per cent of salt, in which concentrations the putrefactive bacteria cannot exist. Nor can their spores develop in media containing as much as 10 per cent of salt.

CHOCOLATE AND CONFECTIONERY

Changes in atmospheric temperature and humidity are liable to produce changes in chocolate and confectionery. The British Food Manufacturers' Research Association has given manufacturers a great deal of help in determining the conditions necessary for the production and storage of satisfactory chocolate. In the factory, it is generally possible to secure these conditions, but in retail premises it is not so easy. If the manufacturer were able to deliver his goods direct from his warehouse to the consumer, defective products would not be so commonly seen as they are at the present time.

Conduction of Electricity in Solids

CONFERENCE AT BRISTOL

A CONFERENCE on the "Conduction of Electricity in Solids" was held at Bristol on July 13-16 under the joint auspices of the Physical Society and the University of Bristol. The discussions were opened by R. W. Pohl, who gave an account of the fundamental work on electron conductivity and photochemical processes in alkali-halide crystals carried out in his laboratory at Göttingen. The paper was mainly concerned with the properties of crystals which have been coloured either by heating in alkali vapour or in other ways, introducing colour centres called '*F*-centres'. A discussion followed on the exact nature of these *F*-centres, and, although there is as yet no certainty on this point, a hypothesis was proposed which seemed to have a good deal to recommend it, namely that an *F*-centre is an electron localized at a point in the lattice where a negative ion is missing.

Papers on phosphorescence in halide and sulphide crystals were given by R. Hilsch (Göttingen) and J. T. Randall (General Electrical Co., Ltd.) who discussed to what extent this phenomenon is related

to photoconductivity and to the transference of an electron to a large distance from the phosphorescent centre.

J. H. de Boer (Eindhoven) gave a paper by himself and E. J. W. Verwey on semi-conductors with partially filled *3d*-bands. He pointed out that the electron theory of metals in its present form is not applicable to a substance such as nickel monoxide, in which a 'band' of electron states is incompletely filled, and therefore ought to behave like a metallic conductor, but which has in fact a resistance some 10^6 times greater than a metal. Both he and R. Peierls gave indications of the way in which the theory would have to be modified to include these substances.

Subsequent papers dealt with conduction in metals. G. Borelius gave an account of the work carried out at his Institute in Stockholm on the resistance of alloys, and especially of alloys in which the atoms can take up an ordered or disordered arrangement. His own pioneer work on the treatment of this problem from the point of view of thermodynamics

described. W. L. Bragg gave a paper by himself, Sykes and A. J. Bradley on the work carried out at Manchester on the same problem.

C. H. Desch (National Physical Laboratory) gave a paper on age hardening alloys with special reference to their resistance. A. J. Bradley also mentioned his recent work on the crystal structure of the permanent magnets in the iron-nickel-aluminium alloy series, and in consequence of this a very definite model was proposed for the age hardening process, the atoms present in solid solution being supposed to collect together in groups still forming part of the crystal lattice of the original alloy. Such a process sets up intense strain, and hence hardens the alloy.

The final day was devoted to a discussion of the resistance of thin metallic films. After an initial paper by G. I. Finch (Imperial College of Science and Technology) on the structure of these films as revealed

by electron diffraction, E. T. S. Appleyard gave a paper on work carried out in Bristol on their resistance, and A. Féry and M. J. Bernamont followed with papers on work done in Paris. A distinction was drawn between metals such as the alkalis which may form a fairly uniform layer over the surface upon which they are deposited, and metals such as mercury which apparently form islands. The mechanism by which the atoms can wander on a surface and form islands was discussed by J. E. Lennard-Jones. A point upon which no agreement was reached was the negative temperature coefficient of resistance of some films, and whether it is due to occluded gases.

Full reports of the principal papers given at this meeting, together with a summary of the discussions and the main conclusions reached, will be published in September in a special number of the *Proceedings of the Physical Society*.

Beginnings of Western Science in Japan

AT the fellows' dinner held at University College, London, on April 30, Prof. Joji Sakurai, meritis professor in the Imperial University of Tokyo, president of the Imperial Academy and of the National Research Council of Japan, replied to the toast of the new honorary fellow. In the course of his remarks, Prof. Sakurai said:

"If what I have been able to do in my work in Japan is at all creditable, the credit must be traced back to my education in England and, first and most of all, to the scientific training I received in University College during the five years extending from 1876 until 1881. Dr. Alex. W. Williamson, renowned throughout the whole world for his classical investigation on the formation of ethers and renowned also for his remarkably keen insight into the atomic constitution of matter, was then professor of chemistry, and it is needless for me to say how highly I value the scientific training I received from him. I was taught physics by Prof. Carey Foster and Dr. Oliver Lodge, and the knowledge of physics has acquired was a great help to me in following the remarkably rapid development of physical chemistry which was soon to come.

"It was, however, not the scientific training alone that I received in England. The five years of my student life in England were in the latter half of Queen Victoria's reign, a period which is one of the most glorious in the whole history of England. It was a period in which some of the greatest and most illustrious of men and, also, of women were to be met with in almost every field of human activity. As statesman and orators, Lord Beaconsfield and the grand old man—Mr. Gladstone—were shining like stars of first magnitude; Tennyson was being adored as poet laureate, Ruskin as a writer and critic and George Eliot as a feminine novelist of unusual talent; Charles Darwin was enjoying to see his life-long labours bearing fruit, Herbert Spencer was laying a scientific foundation of sociology, whilst Henry Irving and Ellen Terry were, night after night, drawing crowds of enthusiastic audiences to the Lyceum.

"Having had the rare fortune of being in England at such a glorious time, I could not, and would not,

confine myself to scientific studies alone, but wishing to look upon England with more widely opened eyes I studied something of English history, of English literature, of English art and, even, of English drama. At the same time, I had the great good fortune of making some very dear and life-long friends and, through them, of knowing something of English homes and of mixing more or less in English society, all of which combined in enabling me to get a fairly accurate idea of English culture, and it was this—the knowledge of English culture—which has proved to me to be of inestimable value throughout the whole of my later life. If, therefore, my work in Japan is worth mentioning, it is to be wholly attributed to the scientific and cultural training I was able to receive during the five years of my student life in England.

"I should like to make a short reference to an important fact in the recent history of Japan, concerning Anglo-Japanese cultural relations. A few years before the Restoration, that is about seventy-five years ago, a group of five young men from Choshu came over to London in one of the sailing vessels owned by Messrs. Jardine, Matheson & Co. of Yokohama, whose correspondents in London were Messrs. Matheson & Co. The object of these young men was to make a general study and observation of Western civilization and when, after a long voyage round the Cape of Good Hope, they arrived in London they were introduced to an elderly gentleman who took every care of them and helped them in every way in their study and observation. This elderly gentleman was no other than Dr. Williamson of University College under whom, as I said before, I was a student for five years. As to what made him particularly interested in these young men and in Japan I can say nothing, but I remember him often telling me that Japan was England of the East, by which, as it appeared to me, he meant something more than mere geographical likeness of the two island empires.

"Returning to the five young men, two of them went back to Japan in the following year in consequence of important developments at home, and

plunged themselves in the great political turmoil which soon led to the Restoration. One of these two men was Shunsuke Ito—later, Prince Hirobumi Ito—who was generally regarded as the founder of modern Japan, and the other was Bunta Inoue—later, Marquis Kaoru Inoue—who was cabinet minister in the Meiji Government on several occasions. The other three also greatly distinguished themselves and occupied important positions in the new Government. Of these, Yasuke Nomura—later, Viscount Masaru Inoue—who, by the way, was living with Dr. Williamson's family for several years, laid out and ran the first railways in Japan, Yozo Yamao—later, Viscount Yozo Yamao—greatly contributed towards laying the foundation of technical education, and Kinsuke Endo was, if I remember rightly, the first master of the mint.

"Now, the most important item in the policy of the Meiji Government was the transplantation of Western sciences, the elements of which were taught by missionaries. But as time came for higher scientific education, need was felt for teachers properly equipped with the necessary knowledge and ability, and the Government naturally decided to call these teachers from England. Strange as it may appear to-day, these calls were made through the firm of Messrs Jardine, Matheson & Co. in Yokohama, which transmitted them to their correspondents in London, and the latter invariably consulted with

Dr. Williamson or somebody else named by him. The fact that Dr. Williamson intervened in this transaction of this important business was most fortunate for Japan, for the young scientific men recommended by him, either directly or indirectly for the Japanese posts all proved themselves to be most capable teachers of science, among whom the names of William Ayrton, Edward Divers, Alfred Ewing, John Milne and John Perry may especially be mentioned as those who, later, all became fellows of the Royal Society of London. These pioneers of science in Japan taught their students to study science for its own sake, themselves setting example by numerous brilliant researches and thereby greatly stimulating the spirit of original scientific work. I am particularly happy to have been given an opportunity this evening of making reference to this little piece of history, which is almost completely unknown but which shows how much Japan owes to Dr. Williamson and, through him, University College and England for the valuable help given in the early and most important stages of development of modern sciences in Japan.

"Ever since the foundation of Ramsay fellowships in 1920, Japanese Ramsay fellows have, if I remember rightly, without a single exception come to work under Prof. Donnan, with whom the cultural obligations Japan owes University College and England have thus been happily revived".

International Association for European Ethnology and Folklore

CONFERENCE AT EDINBURGH

THE International Association for European Ethnology and Folklore was formed in November, 1935. Its first Congress was held in the New College, Edinburgh, on July 14-21. The Scottish Anthropological and Folklore Society acted as hosts.

Seventy-six delegates registered as members of the Congress, the countries represented being Great Britain and Ireland, Sweden, Norway, Denmark, Finland, Lithuania, Estonia, Holland, Belgium, Switzerland, and the United States.

At the opening of the Congress, the presidential address was delivered by Prof. Herman Geijer, of the University of Uppsala. Thirty-one papers were read. Those dealing with folklore included "Remarks upon Methods of Surveying and Making Distribution Maps in the fields of Dialect and Folklore", by the president; "Scottish and Norwegian Ballads", by Prof. K. Liestøl, Oslo; "Norwegian and Gaelic Folklore", by Dr. R. Th. Christiansen, Oslo; "The Stars in Eskimo Folklore", by Prof. W. Thalbitzer, Copenhagen; "Rites", by Dr. C. W. von Sydow, Lund; and "The Origins of the Ducking-stool", by Prof. J. W. Spargo, Northwestern University, U.S.A.

Papers of technological and museum interest were "Simple Agricultural Implements of England", by Mr. R. U. Sayce, Manchester; "The Early History of Vehicles in Northern Europe", by Dr. G. Berg, Stockholm; "The Irish House", by Dr. Åke Campbell, Uppsala; and "Scandinavian Folk Museums", by Prof. Sigurd Erixon, Stockholm.

On the linguistic side, Dr. W. Grant, Aberdeen dealt with "The Scottish National Dictionary"; Mr J. C. Catford, Edinburgh, with "Scottish Dialect and the Proposed Linguistic Atlas of Scotland"; Dr G. S. Lowman, Brown University, U.S.A., with "The Linguistic Survey in the U.S.A. and Canada". Dr. R. Nordenstreng, Uppsala, made some helpful suggestions as to the solution of an ethnological problem in his paper on "The Riddle of the Finns Frisians, and Fair Broad-heads".

Among papers of particularly Scottish interest was that by Mrs. M. Macleod Banks, president of the Folklore Society, on "The Three Maries and the Mary with the Withy".

During the Congress, a 'ceilidh', arranged by Miss J. Bruce, secretary of Highland Home Industries Ltd., was performed by a group of Gaelic-speaking women; and a display of authentic Scottish country dancing was given at Roslin by a team of 'bondagers' under the supervision of Mr. Ion C. B. Jamieson.

Throughout the congress, there was on view an exhibition of ethnological and folkloristic material, of which the outstanding feature was the display of photographs and drawings of house-types and domestic and agricultural implements selected from the collection of the Irish Folklore Commission. Other exhibits were by the Landsmuseet, Uppsala; the Nordic Museum, Stockholm; H.M. Office of Works; and Highland Home Industries Ltd.

University Events

LONDON.—Sir Robert Pickard, director of the British Cotton Industry Research Association, and member of the Senate since 1926, has been elected vice-chancellor for the remainder of the year 1936-37 and for the year 1937-38. He succeeds Mr. H. L. Mason, who took up his duties as principal on July 1. Prof. J. C. Philip has been appointed deputy vice-chancellor for the year 1937-38.

Dr. William Wardlaw has been appointed to the University chair of physical chemistry tenable at Birkbeck College as from October 1. Since 1918 he has been on the teaching staff of the University of Birmingham and has held the post of senior lecturer in chemistry since 1926.

The title of professor of morbid anatomy in the University has been conferred on Dr. G. R. Cameron (Melbourne), in respect of the post held by him at University College Hospital Medical School, and that of reader in chemistry in the University on Mr. Henry Terrey, in respect of the post held by him at University College.

The degree of D.Sc. has been conferred on the following: G. P. Crowden, university reader at the London School of Hygiene and Tropical Medicine (applied physiology), G. E. R. Deacon (chemistry), I. S. Hartley (chemistry), H. L. Chhibber (geology), Dr. W. F. Whittard (geology), Marion G. Eggleton (physiology), T. H. C. Taylor (entomology), R. A. Fraser (mathematics) and H. O. Bull (zoology).

MANCHESTER.—Among the numerous appointments announced at the end of this session is one of somewhat unusual interest—that of Mr. A. D. Ritchie, at present lecturer in physiological chemistry, to the Sir Samuel Hall chair of philosophy and public administration in succession to the late Prof. J. L. Stocks. Mr. Ritchie took first-class honours in philosophy at St. Andrew's in 1911, and second-class honours in Part I Natural Sciences Tripos at Cambridge in 1914. He was elected fellow of Trinity College, Cambridge and worked on the philosophy of science, and was Tarned Lecturer in 1935. Though for the last twenty-three years he has been professionally engaged as a teacher of physiology, he has published various philosophical works in this period.

The following further appointments have also been announced: Prof. P. M. S. Blackett, professor of physics in Birkbeck College, University of London, to succeed Prof. W. L. Bragg in the Langworthy chair of physics; H. Davenport, P. Du Val and W. W. Sawyer, assistant lecturers in mathematics; G. D. Rochester, assistant lecturer in physics; D. G. Evans, assistant lecturer in chemistry in the Department of Bacteriology; E. L. Patterson, assistant lecturer in anatomy; and Miss Margaret I. Williams, assistant lecturer in applied physiology.

SHEFFIELD.—The following appointments have recently been made: J. W. Watson to be assistant lecturer in geography; Gilbert Forbes to be lecturer in forensic medicine; J. M. Kennedy to be lecturer in infectious diseases; G. A. de Belin to be assistant lecturer and research assistant in the Department of Metallurgy.

ST. ANDREWS.—A lectureship in political science has been instituted in the United College, St. Andrews, and Mr. J. M. Brown of Glasgow has been appointed to the new post. Mr. B. S. Robertson has been appointed lecturer in regional anatomy in University College, Dundee.

Science News a Century Ago

The Diet of Silkworms

At a meeting of the Paris Academy of Sciences on July 31, 1837, reported in the *Gazette Médicale de Paris* of August 5, MM. Moriset, de Clavaison and Durrand recorded the results of an experiment on the feeding of silkworms by substituting for mulberry leaves those of the Spanish *scorsonera*. The silkworms which had been so fed from the time that they had been hatched did not appear to suffer from this diet, and had produced cocoons which were in no way inferior to those of silkworms which had been given mulberry leaves at the same time. Some of the cocoons had been sent to the Academy, but did not appear to competent judges to be the product of healthy silkworms. Similar trials had previously been made at different times with the leaves of *scorsonera*, and had always been abandoned. In any event, what had encouraged the speakers to pursue the experiment was the fact that the silk industry would never acquire a great development in the south of France so long as silkworms were fed exclusively by mulberry leaves, in view of the fact that cultivation of the mulberry tree did not harmonize with the other principal cultivations in the country; whereas cultivation of *scorsonera* did very well and would yield a double profit, the root forming a wholesome food similar if not preferable to salsify root.

Hospitals in Russia

A PAPER in the *British and Foreign Medical Review* of July 1837 on the present state of medicine and medical institutions in Russia by Dr. George Lefevre, late physician to the British Embassy at St. Petersburg, contains the following account of the hospitals in that country: "Although few countries can boast of finer institutions for the sick and infirm than Russia at the present day, it has nevertheless been the work of nearly two centuries to bring them to their actual state of perfection. Commenced by a private individual, whose example was soon followed by Government, they only began to have a character of importance under Peter the Great. . . . As regards the external appearance of the hospitals in Moscow and St. Petersburg, they are splendid in the extreme, resembling more the palaces of princes than the abodes of the sick. But it is of their discipline we have to speak, and many of the regulations of these institutions are worthy of imitation by similar establishments in other parts of Europe. One great advantage they possess over charitable institutions of a similar kind in England is the daily admission of patients, the vacant beds being immediately occupied by the most urgent cases. All applicants are not admitted indiscriminately into the General Hospitals; for there are others devoted to the reception of particular diseases, as eruptive fevers, venereal diseases, etc., and persons labouring under diseases which are considered incurable are not treated in the hospitals but are admitted to almshouses. . . . As regards the internal arrangements there is no cause for complaint. The wards are spacious and lofty, the beds not too much crowded together and cleanliness is carried to a point almost deserving of ridicule. . . . The most decided defect in all these institutions is a thorough disregard of ventilation."

The Botanical Society

At a meeting of the Botanical Society held on August 3, 1937, the secretary read a letter from the Botanical Institution of Brussels requesting it might be admitted into friendly correspondence with the Society. Mr. Dannes then read a paper entitled "Observations on the Structure and Germination of the Reproductive Organs of *Marsilea*". The paper was accompanied by a translation of a memoir on the same subject, made to the Paris Academy of Sciences by MM. Mirbel, Dutrochet and St. Hilaire. In *M. quadrifolia* (which much resembles our common trefoil, excepting in its petals being furnished with an additional leaf) there is apparently a longitudinal membranous partition, containing a number of cells each enclosing an hermaphrodite flower. The stamens of these flowers are stated by Jussieu, who was the first to examine the plant minutely, to be so small, and in such numbers, as to render it impossible to count them: they open transversely, to scatter the grains of the spherical yellow pollen. Convincing proofs were adduced from the researches of Dutrochet and St. Hilaire especially, that germination takes place by the impregnation of the ovules with the antheric dust, although this has been strongly opposed by other botanists, who keep all the species of *Marsilea* in the class Cryptogamia.

The *Athenaeum* and Meteorology

In its issues of August 5 and 12, 1937, the *Athenaeum* devoted several pages to an essay on meteorology, the subject being suggested by a review of two recently published works. The first of these was by Patrick Murphy (1782-1847), and was entitled "Meteorology considered in its Connexion with Astronomy, Climate, and the Geographical Distribution of Animals and Plants". Of the author and this book the *Athenaeum* said: "We state our firm conviction, that nothing but loss can be the result of his publishing such books as the one before us". Of the other book, Graham Hutchison's "Treatise on the Causes and Principles of Meteorological Phenomena" the reviewer remarked: "This is a sensible, well-executed compilation, interspersed with some new views and explanations of meteorological facts". The subject was one in which the *Athenaeum* took a particular interest and at the beginning of the essay it said: "If there be one branch of science, more than another, which we have endeavoured to place prominently before the public, it has been Meteorology, because it appeared to us of great importance and to have been especially neglected".

The London Electrical Society

As a result of a resolution passed at a general meeting of the Electrical Society held on August 5, 1937, the Committee issued a report stating that the object for which the Society was formed, as stated in a resolution of May 16, 1937, would be fully carried into effect. The publication of papers had been deferred, as members had intimated their intention of presenting communications, after the recess, containing new facts in electrical science. Among the communications which had already been received was one from Andrew Croese, of Broomfield, near Taunton, describing some results obtained by him in producing crystals by transferring the electrical energy from the zinc and copper plates to other substances not metallic in contact with them.

Societies and Academies

Paris

Academy of Sciences, May 31 (*C.R.*, 204, 1597-'692).

JULES DRACH: The logical integration of lines differential equations: the reduction of the group

MARCEL DELÉPINE and ALAIN HORNAU: The catalysis of the Cannizzaro reaction by active nickel and platinum. The application to some aldoses. The conversion of an aldehyde into alcohol and acid by alkali (Cannizzaro reaction) is greatly accelerated by the addition of a catalyst, Raney nickel or platinum. Results are given for galactose, glucose and arabinose.

PAUL VINCHENSI: The reconstitution of the ensemble of convex bodies of n dimensional space starting from certain base sub-ensembles.

ARNAUD DINJOY: A theorem of Mandelbrojt.

JOSEPH CHALOM: Reaction pumps with supersonic flow.

ASSÈNE DATCHEFF: The solution of Schrödinger's equation.

JEAN LOUIS DESTOUCHES: The relativistic wave mechanics of systems and the interaction of light and matter.

HENRI MINOUR: Clusters of stars in kinetic equilibrium.

PAUL BOURGEOIS and JACQUES COX: The frequency of the concentrations in extra-galactic nebulae detected by Hubble's tests.

LUIGI D'AZAMBUJA: International co-operation for the continuous observation of the sun, and its first results. A summary of results obtained between July 1, 1935, and December 31, 1936. Study of the connexion between chromospheric eruptions and electrical and magnetic disturbances on the earth.

PIERRE VERNOTTE: How to formulate empirical laws. The exponential development.

HENRI LEMONDÉ: The interpretation of variation of viscosity with concentration in binary liquid mixtures.

RENÉ LUCAS: The thermal waves of liquids.

RENÉ PLANIOL: The application of molecular jet to the production of light ions.

JEAN P. E. DUCLAUX: The anodic polarization of tungsten. Study of the electrolysis of sulphuric acid with tungsten electrodes. The fall of current with time, due to the formation on the anode of a layer possessing a high resistance, depends on the condition of the surface, and is independent of the current.

VITOMIR H. PAVLOVIĆ: A new method for studying subjectively the mixture of colours.

MAURICE PARODI: Study of the transmission of some oxides in the extreme infra-red. Measurement for the oxides of manganese, strontium, cadmium and barium are given. The wave-lengths of the absorption bands plotted against the atomic number fall on a curve resembling a parabola.

HENRI BIZET and BELLING THAI: The magnetic rotatory power of compressed and of liquefied nitric oxide, NO. The experimental results suggest that the molecules of nitric oxide commence to polymerize under high pressure at -80°C . From the Verdet constant at -163°C , it is concluded that 93 per cent of the liquid is in the state of double molecule (NO)₂, and this agrees with the results of Rice, based on the entropy of vaporization.

P. BONNET-MAUBY: The utilization of photo-elements with semi-conducting layer for radioactive measurements. Selenium, or copper photo-cell

radiated with α - or β -rays, give rise to a difference of potential, exactly as with photons; the γ -rays have given no appreciable effect. The local variations of sensibility and the effects of fatigue of the element are more marked with α -rays than with photons.

M^{lle}. JULIETTE GAVOYET: The quantitative study of the adsorption of metallic cations by cellulose. The iso-electric point of cellulose.

M^{lle}. SUZANNE VEIL: The potential gradient of gelatine under electromotive force.

CASIMIR JAUSSEMAN: The anomalies of the dispersion of light by colloidal solutions of silver. Although the heterogeneity of the medium studied produces special optical properties, its refractive index can be calculated utilizing for the dispersed metal the same optical constants as those of the metal in the massive state.

M^{lle}. MARIE THÉODOROSCO: The study by the Raman effect of two molybdotartaric complex compounds in water. The results are in agreement with those found by the rotatory polarization, namely, the existence of two complex compounds, $\text{Na}_2(\text{TH}_2\text{MoO}_4)$ and $\text{Na}_2(2\text{TH}_2\text{MoO}_4)$.

CH. BÉDEL: The determination of the solubility of slightly soluble electrolytes, precipitated and in the presence of their reaction products. Application to silver chloride.

MICHEL CYMBOLISTE: The structure of electrolytic chromium.

PIERRE MASTAGLI: The reducing and condensing action of alkaline benzylates on ketones and aldehydes, and on the α , β unsaturated alcohols.

M^{lle}s. MARTHE MONTAGNE and MARGUERITE LARRY: The action of organo-magnesium compounds in the phenylimino derivatives of benzil.

CHARLES BOUHET: The Raman effect in circularly polarized light in quartz, observed along the optic axis.

LOUIS DUBRETHET: The constitution and genesis of the green Syrian rocks.

DANIEL BARBIER, DANIEL CHALONGE and ETIENNE VASSY: The variations of temperature of atmospheric zone according to its origin.

JOSUE HEILMANN HOFFET: The genus *Trigonoides*, a stable genetic mutation of the genus *Trigonia*.

ANDRÉ EICHHORN: Chromosome enumeration and the study of mitosis in two *Crotalaria*.

JEAN TROCHAIN: A new graphical representation of the results of physical and granular analyses of the soil.

M^{lle}s. MARGUERITE COMBES: The probable existence of a higher class, not differing in appearance, forming the true workers in the Formica.

TOHOU SU and CHEN-CHAO-HSI: A new Chinese race of *Acaris megalocephala* (type *trivaleus*).

PIERRE P. GRASSE: Aberrant spermiogenesis of the Metatermitides.

JEAN VILLARD: Geographical variations of the venom of the South American rattlesnake, *Crotalus orificus*.

HENRI BIERBY: Protein sugar and blood proteins in the normal and pathological states.

V. A. KOSTITZIN: A generalization of the biological equations in the case of a population intoxicated by the products of its chemical activity.

JEAN LAVOLLAY and M^{lle}s. FRANÇOISE LABOHEY: The mathematical expression of the development of *Aspergillus niger* as a function of the concentration of magnesium of the nutritive medium.

MARIUS CHADEFAUD: The organization and the richocytes of *Gonyostomum semen*.

HENRI SIMONNET, GUSTAVE GUITTONNEAU, GERMAIN MOOQUOT and ANDRÉ EYRARD: The influence of pasteurization in the absence of air on the nutritive value of milk. The experiments described lead to the conclusion that pasteurization in the absence of air is not incompatible with the preservation of the essential nutritive qualities of milk.

Amsterdam

Royal Academy (Proc., 40, No. 6, June 1937).

L. S. ORNSTEIN: Scattering of neutrons in matter (5). A discussion of the distribution of the directions of motion of neutrons scattered by protons.

J. A. SCHOUTEN: The differential geometry of the groups of contact transformations (3). Infinitesimal doubly homogeneous contact transformations and their applications to mechanics and electrodynamics.

F. M. JÄNGER, J. A. BOTENMA and E. ROSENBOHM: Exact measurement of the specific heats of metals at high temperatures (28). The heat capacity and the electrical resistance of didymium between 300° and 600° C.

F. M. JÄNGER and J. TER BURG: On pterotactic derivatives of bivalent platinum with optically active cyclic trans-1.2 diamines.

A. G. VAN VERN and J. K. BAARS: Constitution of toxoflavin. This substance, produced by the action of *Bacterium cocovenenans*, is a di-imine containing the purine skeleton and is isomeric with methyl-xanthine.

O. POSTHUMUS: Some remarks on the vegetation on the sandy soil of the Pandang Loewai (E. Koetai, E. Borneo).

S. W. VISSER: A period of twenty-seven months in the rainfall throughout the world.

W. B. DEYS and M. J. DIJKMAN: Splitting off of gallic acid from tannin, especially from theotannin by *Aspergillus niger*.

M. J. ADRIANI: Transpiration of some halophytes cultivated in various media in comparison with that of some non-halophytes.

H. J. HARDON: Padang soil, an example of podsol in the tropical lowlands.

G. C. HIRSCH and R. F. J. VAN PULT: Rhythm of the glycogen content of the liver of the white mouse.

M. J. L. DOLS, B. C. P. JANSSEN, G. J. SIZOO and J. DE VRIES: Studies on phosphorus metabolism in normal and rachitic rats with a radioactive phosphorus isotope (see also NATURE, June 19, p. 1068).

J. J. DUYVENÉ DE WIT: Biological evidence of two new hormones by tests on *Rhodosus amarus*.

Cape Town

Royal Society of South Africa, May 19.

K. F. M. BRIGHT: The South African inter-tidal zone and its relation to ocean currents. (2) An area on the southern part of the west coast. (3) An area on the northern part of the west coast.

R. F. LAWRENCE: The odoriferous glands of South African harvest spiders. The external appearance of the odoriferous glands in some South African harvest spiders is described, as well as the colour, volatility, and smell of the secretion of the glands. The activity of the glands is considerably more marked in the large group of Laniatores, some members of which expel the secretion in the form of a fine jet. The ejection of an evil-smelling substance is most probably a defence reflex in this group of Arachnida.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

ASSISTANT LECTURER IN ZOOLOGY in the University College of North Wales, Bangor—The Registrar (August 7).

TEACHER OF ENGINEERING in the Oxford Schools of Technology, Art and Commerce—The Chief Education Officer, City Education Office, 77, George Street, Oxford (August 14).

LECTURER IN MECHANICAL ENGINEERING in the Coventry Technical College—The Director of Education, Council House, Coventry (August 23).

JUNIOR METALLURGIST for the British Non-Ferrous Metals Research Association—The Secretary, Regent Buildings, Weston Street, N.W.1.

Systematics in Relation to General Biology

THE classification of living things is of prime importance, and fundamental to any biological research. Taxonomy, the law of order, is not only one of the oldest branches of biology, but also remains one that is basic to such more recently developed branches as cytology, ecology, and genetics. This fact cannot be too much stressed. It is somewhat unfortunate that a really satisfactory history of plant and animal taxonomy remains unwritten. The philosophical and logical principles underlying classification have also not received the consideration they deserve, and taxonomists themselves are often ignorant of the real implications of the working hypotheses they adopt. They are often also none too clear as to exactly what is implied by certain words and phrases, such as 'phylogeny' and 'a natural system', which have perhaps assumed a 'blessedness' they scarcely deserve.

Text-books of systematic biology, with very few exceptions, still define the aim of a natural classification as the reconstruction of the course of evolution, and seem to envisage the possibility of eventually producing a schematic tree on which each group hangs on its appropriate branchlet. That this conception rests on a confusion of thought has been suggested by many biologists, and its continued unqualified statement in taxonomic text-books is to be regretted. Perhaps the fullest discussion of the difficulties of equating a natural with a phylogenetic classification is contained in the late Dr. F. A. Bather's presidential address to the Geological Society in 1927, and the same point was stressed recently by Mr. J. S. L. Gilmour in his article "A Taxonomic Problem" in *NATURE* of June 19, p. 1040. Clear thinking on this fundamental issue is one of the most urgent needs

for the future progress of taxonomic work. The older, 'orthodox', taxonomy is based mainly on morphology (including, especially for some groups, anatomy) and with the supplementary use of geographical data, notably in higher animals. This use of morphological criteria as the basis of classification has yielded remarkably valuable results, of which taxonomists may well be proud. There is also no doubt that much yet remains to be done along the well-recognized lines of morphological description and classification, especially in many groups of invertebrates and lower cryptogams and among the faunas and floras of relatively little-explored parts of the world. It will further be generally allowed by taxonomists that there is still room for improvement in their methods of comparative description, terminology, and details of classification without involving far-reaching changes.

Within the last two decades, however, there has not only been an almost startling advance in cytology, ecology, genetics, and other sub-sciences of biology, but it has also become increasingly recognized that many discoveries classified under these heads have a bearing on orthodox taxonomy. This impact of newer methods on the still essentially morphological systems of naming and arranging animals and plants can no longer be ignored. It concerns all biologists, whatever may be their particular fields of research. There is no general agreement as to whether new subsidiary systems, with their own terminology and symbolism, should be developed as independently as possible of existing taxonomy, or whether the latter can be so expanded as to include those data of cytology, ecology, genetics, etc., that can be used as 'characters' for arranging organisms into groups.

Orthodox taxonomy has developed International Rules of Nomenclature. The use of these within their proper field is not disputed, but they may, in their present form, prove a hindrance if rigidly applied to an expanded taxonomy. The possibility and desirability of developing an all-inclusive taxonomy towards an ideal state of perfection needs full investigation.

Existing taxonomy is based on grouping animals and plants into taxonomic units termed varieties, subspecies, species, genera, families, etc. There is, however, considerable disagreement, even among specialists within one group, as to the limits of the units. A general survey of the systematic categories in different groups, a classification of the criteria used, and a careful consideration of recently discovered cytological and genetical facts might well lead to obtaining greater precision, more logical arrangement, and greater uniformity in taxonomy.

Taxonomic literature is very large, scattered in many periodicals, and very diverse in presentation and contents. Museums, herbaria and other institutions contain quantities of material and data, available to the biologist, but often not in a readily accessible form for any particular piece of research. There is, indeed, an almost unrealizable mass of material and of known facts which would yield results of the greatest biological importance if only they were collated and correlated with the rest of biology. It is to be anticipated that new generalizations of considerable importance will emerge in the process. Some of the preliminary analysis has been done, but the results are scattered and uncorrelated; the synthesis would seem to await another Darwin. The task, however, is now beyond the physical powers of any one individual.

- While taxonomy is at present based mainly on morphology, its history shows that attempts have been made from time to time to incorporate new ideas.* Thus, though taxonomy long antedates the general acceptance of the evolutionary principle, this had in time considerable effects on taxonomic theory and practice. Similarly, especially at the species level, peculiarities of distribution have been utilized in drawing limits between groups.

Of recent years, it has become increasingly evident that speciation is neither invariably a simple, clear-cut phenomenon nor due to any one cause or series of causes: rather, a number of factors, internal and external, operate in producing speciation and other evolutionary processes. Their relative importance in different groups needs

intensive and extensive investigation. Again, many relevant facts have been published, but until the scattered data have been extracted, correlated and classified, it is impossible to tell along what line and with what material new research is most likely to throw light on those questions of equal importance to the taxonomist, cytologist, ecologist, and geneticist. It is certain, however, that a great deal of new research is necessary before the problems even of speciation can be solved. The development of biology along synthetic lines does not mean the abandonment of analytical methods in special research. It means rather their intensification, but with a co-ordination at present largely lacking. The collection of material for the eventual publication of a British Fauna and a British Flora on uniform and broad biological lines should serve as a stimulus to research and as a focus for co-ordination.

Many kinds of biological research involve the recording and interpretation of large masses of facts. With proper help and advice, valuable work can be done by local societies, amateurs, schools and colleges. Such research, properly conducted, can have a twofold value: observations or experiments can be made over a wide area or for a long period of time; and they are of very considerable educational value to the persons making them.

Taxonomists, and indeed other biologists, frequently complain that their subject is not well taught in universities and schools. There is much truth in this complaint, and the modification of teaching methods and syllabuses is an urgent need. Students not infrequently know much about the anatomy of a plant or animal without knowing anything about it as a living organism or its relationships to other organisms. The revivification of taxonomy by expanding its scope to include data from other branches of biology and the realization of what they can gain from taxonomy would in itself tend to encourage greater attention to its careful teaching.

That the time is ripe for increased co-operation between workers in different branches of biology will, it is hoped, be acknowledged. In this connexion the recent formation of an "Association for the Study of Systematics in Relation to General Biology", an account of which was published in *NATURE* of July 24, p. 163, is of special interest. The work of the Association should do much to stimulate interest and co-operation in the various aspects of the impact of modern biological thought on the problems of taxonomy.

Indian Ethnography

The Khārīās

By Sarat Chandra Roy and Ramesh Chandra Roy. Vol. 1. Pp. xv+306+27 plates. Vol. 2. Pp. i+307-530+lviii+13 plates. (Ranchi: "Man in India" Office, 1937.) 11 rupees.

STUDENTS of tribe and caste in India are well acquainted with Sarat Chandra Roy's excellent studies of the wild tribes of Orissa and the Central Provinces, of which the results are contained in his works on the Mundas, Oraons, Birhors and Bhuiyas. We are now given two interesting volumes on the Khārīās, who are to be found in Orissa and the eastern portion of the Central Provinces. Following the established order of such works, particulars are given of the origin, migration, physical traits, culture, social organization, birth, marriage and death rites, festivals and superstitions. Dr. Marett gives the work a short introduction, and there are numerous illustrations.

There are three branches of these primitive people, the Erenga or Hill Khārīās, the more civilized Dudh Khārīās, and the Delki or Dhelki Khārīās. The Hill section of this tribe still live by a system of cultivation known as *Jhum* in the eastern and *Kumri* in the western provinces of India. This consists in burning down large tracts of forest and sowing scanty crops in the ashes. As the forest is destroyed by this process, the population moves to fresh areas for a source of livelihood. The other divisions of the tribe have adopted more settled forms of agriculture.

The two large volumes containing the fruits of Sarat Chandra Roy's research offer, as was to be expected, much resemblance to the accounts of similar tribal units in other parts of India. We find traces of totemism, a system of ancestor worship, the belief in and propitiation of evil spirits, a form of medicinal treatment based partly on the use of vegetable products and partly on spirit scaring, and a firm belief in omens and witchcraft. The totem section among the Khārīās is known as *Kili* or *Khili*, corresponding to the *devak*, *bedagu* or *bali* of western India. The author gives the name of many totem divisions which apparently bear close resemblance to those of similar tribes in other parts of the country; but here, it may be noted, identification is rendered difficult by lack of adequate description of the tree or animal referred to. The vernacular names are an inadequate guide, particularly in the case of trees which bear many vernacular names in different areas.

In this connexion, special interest is attached to the list contained on pp. 458-460 in vol. 2. The author is here giving his reader the names of a number of trees of which the products are used for medicinal purposes. It will be at once discovered that the botanical names are those of well-known totems of other parts of India, as for example, *Lausonia alba*, *Phyllanthus emblica*, *Achyranthes aspera*, *Artocarpus Lakoocha*, *Bombax malabaricum*, *Eugenia Jambolana* and the well-known *Calotropis gigantea*.

The importance of this list lies in the fact that it has been often assumed that there is a close connexion between the medicinal value of certain trees and their adoption as the totem of an exogamous unit. Significance, therefore, is attached to the fact that among the Khārīās, a very primitive tribe, such value is found in the very same trees that the Marāthas and allied castes hold in totemistic relationship on the other side of India.

Russell, in his "Tribes and Castes of the Central Provinces", pp. 445 *et seq.*, describes the Khārīās as a primitive Kolarian tribe which appear to be allied to the Mundas and Savars. He considers them to be an elder branch of the Mundas. He describes them as very dirty in their persons, with features of a low character, not unlike the Bhumij, but with an absence of any strongly marked type.

In the "Linguistic Survey of India", the Khārīā language has been declared to be closely allied to Savara, and to resemble Korku and Juang. It has ceased to be a typical Munda language, according to Sir George Grierson. Sarat Chandra Roy, as was to be expected from the results of similar investigation in other areas, finds evidence that the first spirits to be personified and deified were those of ancestors. He writes:

"This is why we find among all sections of the Munda tribes, the worship of ancestor spirits. One's parents and other near relatives whom the Khārīā loved and honoured when they were living cannot fail to be regarded with love and reverence after they were dead. Spirits of ancestors who were revered and looked up to as *Sins* or village elders during their life-time are especially remembered and honoured after death" (p. 315).

The late Sir James Campbell, in his notes on the spirit basis of "Belief and Custom" published in the *Indian Antiquary*, held a similar theory, and proceeded to show by numerous examples collected in western India how the original practice

of spirit soaring by various well-known rites developed into a system of spirit 'squaring', whereby suitable propitiation was made to the spirit and a lodging found for him where he would be content to dwell without further troubling the helpless victims of his attention. This process of propitiation for the *Dubo* or ill-disposed spirits is described by Sarat Chandra Roy. In addition to ancestral spirits, as might be expected, Khārīās worship a host of minor deities, of which details will be found in Chapter xi. Above them all is the supreme spirit known as Poromosor, an obvious corruption of the Hindu title of Parameshwar.

We must close this short notice of Sarat Chandra

Roy's valuable work by an acknowledgment of the assistance such studies are to those interested in the Ethnographic Survey of India, now represented by a constantly increasing flow of works of this description. If a word of criticism may be permitted, it would take the form of a regret that so many misprints are allowed to disfigure these pages. They are quite unusually numerous, and, strangely enough, we have a consistent wrong spelling of the well-known name of the author of "Tribes and Castes of the Central Provinces". The illustrations, mostly reproductions of photographs, are greatly lacking in clearness of outline, and thus lose much of their value.

R. E. ENTHOVEN.

Afforestation in the Lake District

Afforestation in the Lake District:

a Reply to the Forestry Commission's White Paper of 28th August, 1936. By H. H. Symonds. Pp. xxi + 97 + 4 plates. (London: J. M. Dent and Sons, Ltd., 1936.) 2s. net.

IT is well known there has been considerable controversy over the afforestation work which has been and is being undertaken by the Forestry Commission. Mr. Symonds has written a small book dealing with the Lake District in this connexion, and Lord Howard of Penrith contributes a foreword. A joint informal committee of the Forest Commission and the Council for the Preservation of Rural England was appointed. The author details the various results of the meetings, the questions asked in Parliament and comments in the Press on the Forestry Commission's proposals.

Opposition to the proposals to afforest parts of the Lake District is based in part on the monotony of scenery introduced by commercial afforestation. "The sitka spruce and Norway spruce—the staple diet of waterlogged ground—Douglas fir, Corsican pine—how they repeat themselves; ages ago they learnt their lesson, and the 'damnable iteration' of them is an offence: they have the air of mass production, the efficiency of the machine." The author states that his book is not an argument against afforestation or conifers. But he points out that while conifer stands, after first youth, may look magnificent on the Alps, Jura or the Rockies, they are out of place in the fells of Cumberland which are on so small a scale that they "depend for their grandeur on a system of

natural proportions which you can spoil, but not alter". As Lord Ullswater has said, the problem is one "of taste, discretion and degree".

If one of the reasons for planting in the Lake District was to give work to the unemployed, it would seem a pity that the Forestry Commission did not avoid controversy, for the work of the forester is exposed to many dangers on an antagonistic countryside, by agreeing to plant broad-leaved trees only, and mixed woodland, as suggested by the author. Some valuable experience would have been obtained on the subject as to the elevation to which some of these species can be taken, and amenity would have been safeguarded; since the forester who knows his job should have been able to adapt his plantings to harmonize with, and not spoil, a piece of countryside the beauty of which has for long been a household word in Great Britain, even amongst many who have never seen it. It would be an interesting piece of work demanding skill and considerable knowledge; a different type of work, it may be admitted, from the monotonous planting of young conifers on a more or less uniform pattern. The question of the longer period the nation would have to wait for a return in money does not appear to be of so great importance in the Lake District, where other advantages are already being reaped.

The author puts up a strong plea for the preservation of the sheep farming and the Herdwick strain, both of which must disappear with any considerable afforestation in the Lake District owing to the fact that of necessity all the lower ground would be planted up, and thus the sheep disturbance would be complete. The Forestry Commission

planting proposals will involve the displacement of more than 5,000 of this local breed of sheep.

Mr. Symonds also deals categorically with the question of the extra unemployed that the scheme would provide for and the question of small holdings. On both these subjects he displays ample local knowledge, and his remarks on the subject of the prospects before the small holder, especially of one unacquainted with the locality, merit consideration.

Mr. Symonds' little book appears to sum up the present position. To many, the Lake District is a thing apart; and when the total area involved and the comparative small size of the conifer woodlands to be established is taken into account, it would appear that the Forestry Commissioners here have the chance of justifying the useful position they have taken in the country by leaving the beauty spots alone, and planting, where planting must be, with hardwoods.

Insect and Allied Pests of Fruits

The Pests of Fruits and Hops

By Dr. A. M. Massee. (Agricultural and Horticultural Handbooks.) Pp. 294 + 27 plates. (London: Crosby Lockwood and Son, Ltd., 1937.) 15s. net.

THE production of profitable fruit crops is dependent upon a variety of factors, some beyond the control of the grower, others being within his control. The factor of pest incidence in an orchard or plantation is one of extreme importance, for while the occurrence of some species—resident pests—are within the plantman's control, others—migratory pests—are to an extent beyond control, and the presence of the latter group are frequently undetected until irreparable damage is committed.

Great advances in fruit culture have been made during the past twenty years, and an increasing number of scientific investigators are engaged upon the elucidation of problems connected with this important industry. Entomologically speaking, the changes have been great both as regards new and troublesome pests, namely, capsid bugs, fruit tree red spider mite, and tarsonemid mites; the appreciation of virus infection and the part played by insects in their transmission; the measures for controlling pests by the introduction of tar-distillate egg-killing washes, petroleum oils, and *Derris* and *Pyrethrum* preparations; and the evolution of high-powered machinery for the application of insecticidal and fungicidal washes and dusts.

It may appear strange that this much-needed volume is only the third standard work dealing with the pests of fruit which has appeared in forty years. To those, however, who are familiar with Miss Ormerod's "Handbook of Insects Injurious to Orchard and Bush Fruits", published in 1898, and with the monumental work of Prof. Theobald, published in 1909, it is less curious, for these

authors produced works which were classics in their particular line.

The present author, while purposely omitting technical descriptions of insects, has attempted to place before fruit-growers and students a simple and brief account of some of the more important insect and allied pests that occur on top and soft fruits and on hops. Simplicity of expression is a matter of degree, and while the specialist may consider the account of the several pests to be simple, the layman may think otherwise.

Technicalities are wisely omitted, but the inclusion of some information relative to the more important orders of insects and allied animals would have allowed the lay reader to appreciate the varied life-cycles, feeding habits, and metamorphoses of the several groups of arthropods mentioned in the text. Again, the inclusion of a simple key, with figures, to the larval stages of insects, would enable the practical man to differentiate between the larvae of the Endopterygota without seeking for such information in the body of the work.

The volume is well illustrated with more than a hundred photographs taken by Mr. R. M. Greenalade, who is Dr. Massee's colleague at the East Malling Research Station. An author would prefer to have the illustrations placed near the description of the pest, and it is unfortunate that publishers frequently fail to attain this desirable end. One example will suffice, namely Plate iv (facing p. 36) illustrates bark beetles and shot hole borers and the damage committed by them, but these pests are described on pp. 181-183—an unfortunate misplacement.

To illustrate insect species without descriptive matter is of little value either to the specialist or to the fruit-grower, for while the former is taught not to depend on an illustration for purposes of

identification the latter is tempted to make his specimen fit the figure. For example, Plate viii illustrates eight species of tortricid moths, but one fails to find any description of the several species on pp. 60-66.

Careful proof-reading has reduced the number of errors to a negligible quantity, and the inclusion of three indexes—scientific, popular, and author—is of immense value both to those who read and to those who scan a textbook.

The author is not hopeful of the standardization of scientific names of insects. The laws of priority must of necessity be obeyed, and as such the standardizing of generic and specific names will take time. The applied entomologist is not blameless in this respect, for he, too, has the habit of changing names; for example, the coccid, *Lecanium corni* Bouché, though long known as the 'peach scale' following its appellation the 'brown scale', is now termed the 'European fruit scale'!

Of the fifteen chapters, eleven deal with fruit pests arranged under their respective hosts, which are arranged alphabetically, and one chapter (xii) is devoted to a review of the pests of hops. Chapter xiii discusses beneficial and harmless insects, while the penultimate chapter deals with insecticides. The final chapter, entitled "Spraying Equipment and Methods", has been written by Mr. J. Turnbull, the Ministry of Agriculture's specialist on the subject.

A limited number of references conclude the

note on each pest described, but the omission of references in the case of Chapter xiv requires to be rectified in a second edition. It is apparent both in the notes on control measures and more especially in the chapter on spraying equipment and methods that the book is written primarily for the fruit-grower rather than for the owner of smaller establishments. This is unfortunate, for the earlier works of Miss Ormerod and Prof. Theobald are examples worthy of assimilation, in that these authors never failed to appreciate the difficulties both of the owner of large plantations and of the amateur gardener.

It is strange to read the author's statement (p. 233) that the 'cauliflower' disease of strawberry is probably due to virus infection, for the work of Dr. Margaret Lacey indicates that a bacterial organism is concerned with this malformation.

Notwithstanding these several criticisms, Dr. Massee, who is recognized as the foremost pomological entomologist in Great Britain, has produced a work of outstanding merit which will long remain a classic. It will be welcomed by the fruit-growing community, the biologist, the student, and by all who are interested in fruit culture. The author has not sought to embellish his story with scientific jargon; the simplicity of phrase, though worthy of emulation, is rare; and Dr. Massee shines despite of it, thereby showing his eminence in the field of biology.

G. FOX-WILSON.

Experimental Optics

Introduction to Optics

By Dr. G. B. Deodhar. Pp. xii + 614 + 21 plates. (Allahabad: The Indian Press, Ltd., 1936.)

THE term 'Introduction' applied to a text-book on a branch of physics gives little idea of the standard and scope of the work. Those who are familiar with the customary method of teaching optics will understand what is implied in this case from the fact that the work is based upon the author's lectures delivered to degree students in the University of Allahabad. It is assumed that the reader is familiar with the elementary principles of physics, such as are taught to pupils during their last school year, or to students during the first year at a university. In Great Britain the work would be regarded as suitable for an ordinary degree course in optics but as falling short of the standard required in an honours course.

The author tells us that he is especially con-

cerned in keeping the experimental side of the subject in the foreground and that the treatment is chiefly non-mathematical in character. The first six chapters are devoted to geometrical optics and the remaining thirteen chapters to physical optics. The book is large, consisting of some six hundred pages, and the syllabus of subjects is complete and adequate.

In the treatment of geometrical optics, the author adopts the Abbé sign convention, which chooses oppositely directed axial directions for the location of object and image. He thus falls in with a custom which is becoming more and more widely adopted. His convention with regard to angles is confusing, and is not necessary. He introduces the reader to the 'principal points' in a simple and interesting manner; but he ought to have elaborated the brief explanation of his points in this connexion. He ought also to have given a fuller account of telescopic systems.

Many practical questions on the investigation of lens systems are treated, and this is certain to be helpful to the student reader. In the treatment of interference, diffraction and polarization, the author keeps very closely to the methods of some well-known writers on the subject of physical optics, and makes use of familiar diagrams. He makes some improvement in the presentation of the formula for the resolving power of the microscope, but again errs by being too sparing in the discussion. The last few chapters are concerned with Bohr's theory of spectra, with colour, photography and the ether experiments.

A work of this kind must be judged to some extent on the basis of the purpose for which it is written, but some general criticisms arise in connection with it. There are several well-known standard text-books on this subject, and a new one ought not merely to add to their number. It must either introduce new matter or present the old in a novel and better way. The present volume does not justify itself on these grounds;

indeed the author accepts the old subjects and methods.

There is also the question as to what the nature of an introduction should be. Is it to introduce the reader to a very wide range of subjects, with the sacrifice of thorough study in the case of most of them, or should it treat a more limited range in which the principles are well illustrated and in which superficiality can be avoided? In this book, with its brief references to subjects not always well moulded into the general plan, the author creates the impression that he is afraid of leaving something out. It would appear that he favours the introduction to a wide range. But at the present time, when all branches of physics are becoming more and more bewildering in detail and extent, students require guidance to those parts of the subject where principles can be soundly grasped. Depth of study is an urgent need, and it is suggested that this book will be improved as an introduction to optics if the author will consider this point in modifying future editions.

Advanced Dynamics

Dynamics

Part 2. By A. S. Ramsey. Pp. xi+344. (Cambridge: At the University Press, 1937.) 15s.

THE publication in 1929 of Mr. Ramsey's excellent dynamics for the use of higher divisions in schools and for first-year students at universities has called forth many requests for similar treatment of the more advanced parts of the subject. The present volume has therefore been written as a continuation of the course so well laid out in the earlier book. It amplifies both the dynamics of the particle and of rigid bodies, and extends the discussion to three dimensions sufficiently far to meet the requirements of an honours degree. It also includes the use of generalized co-ordinates, motion under no forces and the motion of tops and gyrostats. The author has had the advantage of drawing freely from the late Dr. Besant's "Treatise on Dynamics" which was a model of conciseness and lucid exposition, and which, although revised by Mr. Ramsey some twenty years ago, is now out of print.

The plan of the book has been skilfully devised so that the inherent difficulties of the subject may be intelligently surmounted by the average student. There are twelve interesting chapters,

abundantly illustrated by seventy fully worked-out examples, most of which are taken from recent examination papers. This is done to represent the kind of knowledge which is expected of present-day students, but it is apt to confine the subject-matter within somewhat artificial boundaries, especially if the syllabus to be covered is traditionally academic. This, however, is not the fault of any author who sets out to deal with a specific syllabus, and, whilst the content of the present volume is undoubtedly academic, the treatment is thoroughly fresh and stimulating. Practical topics, such as longitude, gyrostats, gyrostatic compasses, etc., are touched upon, though mainly from a theoretical point of view.

The book closes with an appendix on vectors and their applications, for the author does not wholly approve of the principle of establishing the fundamental equations of dynamics by vectorial methods, which he rightly regards as a modern fashion not designed to become permanent.

There is an abundant supply of examples for the use of the student, and each set is roughly divided into two groups, one of easier problems and the other of a more difficult character. The book will undoubtedly be of great value to all students who are training to become mathematical specialists.

F. G. W. B.

The Ancient Burial-Mounds of England

By L. V. Grinsell. Pp. xiii+240+24 plates. (London: Methuen and Co., Ltd., 1936.) 12s. 6d. net.

MR. GRINSELL is an enthusiast about his subject; and although he does not profess to be a scientifically trained archaeologist, if he fails to inspire the reader with his own enthusiasm, it will not be the fault of his excellent descriptions of the barrows of England. He includes all that the amateur will desire to know of the history of the study of barrows, of their types and chronology, of burial customs, of their folk-lore and of their local names. He describes the methods of study in field-work and by excavation. Finally, he gives a detailed topographical list of these monuments, of which the only criticism to be made is that it is more complete for the south of England than it is for the north. The illustrations are good, though small. Brief bibliographies are given for the benefit of those who wish to carry their studies further.

Handbuch der biologischen Arbeitsmethoden

Herausgegeben von Prof. Dr. Emil Abderhalden. Lief. 460. Abt. V: Methoden zum Studium der Funktionen der einzelnen Organe des tierischen Organismus, Teil 10, Heft 6. Allgemeine und vergleichende Physiologie. Eine Verstärkeranordnung zur Registrierung gehirnelektrischer Spannungen, von Rudolf Ottenthal; Neue kataphoretische Verfahren, von Hugo Theorell; Lichtelektrische Zellen und ihre Anwendung für wissenschaftliche Messungen, von Marie Wreschner. Pp. 1075-1234. (Berlin und Wien: Urban und Schwarzenberg, 1936.) 9 gold marks.

THE first paper describes an amplifier designed to work an oscillograph for recording electrical changes in the intact brain. The arrangement consists of a three-stage resistance capacity amplifier containing two pentode valves followed by a triode. The values of the various condensers and resistances are chosen to give a long time-constant, and the author claims an undistorted amplification of 70,500, constant over a frequency range of 10-500 cycles per second.

An interesting application is described in which two amplifiers are simultaneously led off from the same cranial electrodes, thereby giving two oscillograms on the same photographic paper. One instrument responds normally over the complete frequency range, while the other, by means of large capacity condensers arranged in parallel with the anode resistances of the first two stages, amplifies efficiently only at frequencies of 1-10 cycles per second. From the two simultaneous oscillograms an approximate curve analysis is obtained.

The second paper describes an improved type of kataphoresis apparatus in which it is possible to maintain the solution at a constant pH value. Several examples of its application for the investigation of biochemical material are quoted, such as references to work on flavin, Warburg's respiratory co-enzyme, cytochrome c, blood serum, and the anti-pernicious anaemia principle of liver.

In a larger type of apparatus suitable for the purifica-

tion of various substances, the cell has a greater cross sectional area, and parchment paper diaphragms are employed to separate the intermediate buffer solution.

The third paper commences with a fairly comprehensive survey of present-day knowledge of photo-electric phenomena, and includes a number of useful references. This section is followed by detailed descriptions of different types of photo-electric cell and their characteristics. The remainder of the paper is devoted to descriptions of numerous applications including microphotometry, spectrophotometry, colorimetry, nephelometry, pyrometry and polarimetry.

Die mathematischen Hilfsmittel des Physikers:

Von Prof. Dr. Erwin Madelung. Unter Mitarbeit von Dr. Karl Boehle und Dr. Siegfried Flugge. (D Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen, herausgegeben von R. Courant Band 4.) Dritte vermehrte und verbesserte Auflage. Pp. xiii+381. (Berlin: Julius Springer, 1936) 28.80 gold marks.

THIS book falls into two distinct parts: mathematics and physics. The third edition differs from the second (published about twelve years ago) in respect of a more systematic handling of the subjects, the introduction of much new matter, including a chapter on group theory, and a complete rewriting of the chapter on quantum theory. The author's object is to provide for physicists a précis of those parts of mathematics which shall be of direct use and which could only be otherwise obtained by consulting a large variety of text-books. In the second part of the book the equations of mathematical physics are formulated.

The result is excellent as a piece of clever condensation, but one cannot help feeling that to make any adequate use of matter in such concise form—practically no proofs or illustrations are given—the reader will have to consult the text-book after all. For the mathematician or physicist, however, the work affords admirable and useful summaries in their respective subjects.

Faithful Rebels:

A Study in Jewish Speculative Thought. By Dr. Israel Levine. Pp. viii+146. (London: The Soncino Press, 1936.) 6s. net.

IN this work Dr. Israel Levine, the head of the Philosophy Department, University College, Exeter discusses the outstanding contributions to philosophy by Jewish thinkers from biblical times down to the present day. In the oldest writings of Hebrew culture as represented by the Book of Job and Ecclesiastes and the works of Philo and Maimonides little philosophy is to be found, and it is not until the middle of the seventeenth century that Jewish philosophy begins with Spinoza, while in the nineteenth and present centuries Marx represents economic science and Bergson metaphysics. Dr. Levine comes to the conclusion that science and philosophy are not really native to the Hebrew genius, but require for their development the stimulus of alien culture and the raw material of alien contact.

The Natural Philosophy of Paintings

By F. Ian G. Rawlins

IN his inaugural lecture in 1936 as Tait professor of natural philosophy in the University of Edinburgh, Prof. Max Born referred to an essential difference between science and art. Mathematical and physical theories deserve well if they meet the intellectual needs of their period, whereas the creations of great artists are for all time. It might appear from this that mankind is obliged to reckon with continuous change in his scientific concepts, and can hope to find rest unto his soul only in the static nature of art. However this may be, it is no purpose of the present article to insist upon such a distinction, but on the contrary, rather to inquire into the conditions which exist (or may exist) tending to bring the worker in the exact sciences into contact with the world of art and its problems.

One such opening is obvious enough—the task of applied physics and chemistry in assisting the curator in the conservation of paintings, both by a knowledge of materials as such and by devising methods of improving the environment in which objects of supreme value are housed. Progress along these directions is not difficult to trace. There are laboratories specially equipped for such studies at the Fogg Art Museum in the United States, at the Louvre in Paris, the National Museum in Lisbon, and three in London—at the British Museum, the Courtauld Institute (Norman Wilkinson Foundation) and the National Gallery. Much has been learnt at all these places; but it is clear that basic questions relating to the behaviour of paintings in certain circumstances remain unanswered, and that a fair amount of the data so far collected is little more than empirical.

In Great Britain, co-operation with specialist institutions under the Department of Scientific and Industrial Research has proved both interesting and effective. The experiments needed are so many-sided that no one laboratory could expect to cope with more than a fraction of them.

There is another way in which physics and chemistry may help. This is in the prosecution of systematic studies relating to the technique of the old masters: the search for forgeries and their possible establishment are notoriously difficult tasks, but if and when such results are possible, it is not infrequently as a by-product of the careful investigation of painters' methods in general. There is much to be said for the regular use of X-ray analysis to assist the student of art history

in his researches, and as a check upon the conclusions which he may reach on stylistic grounds. It is no part of scientific method to attempt to do what only 'an eye for a picture' can, in the end, accomplish; nevertheless, investigators will not refuse objective evidence when it can be forthcoming. Fortunately, favourable cases do arise.

Yet another possibility can be visualized, difficult as it is. In much the same way as physics and philosophy are to some extent conterminous, so a detailed study of art history leads naturally to the necessity of exploring the mind of the artist, and consequently the outlook of his time. Thus art history and psychology tend to share common ground. Doubtless, a large number of pictures were commissioned and executed according to rigid conditions prevailing in the ideas of the period, yet here and there examples appear which seem to indicate that the work in question was brought into being in the subconscious mind of the artist and is thus a document of the deepest significance. It is a far cry to the day when anything of this nature might conceivably be demonstrable experimentally; what is important at the moment is the infiltration of scientific method into the attempt to effect a closer synthesis between our appreciation of works of art as they are, and the mental and cultural background which produced them. A work of art is an organized whole, possessing shape as well as tone; above all, it is no mere accident, and in its fashioning the artist may be presumed to have given of his best. These conditions approximate to the law of *prägnanz* in the psychology of Gestalt. It may be here that, in the last resort, a natural philosophy of paintings may be found.

The immediate problem is the application of scientific principles to paintings in the matter of conservation, restoration, environment and in the systematic study of technique. A major consideration is that of safety. No risks can be entertained for a moment, and therefore much may have to be learnt upon models, or (by the artificial reproduction of conditions. The essential characteristic of a painting—mural or panel—is its stratified structure. In order, there are (a) the support or carrier, for example, plaster or wood, (b) the ground, (c) the paint film, (d) the surface or varnish film. According to the varying methods of different schools, modifications of this sequence

may arise; but it represents the normal state of affairs, and the one with which the scientific investigator usually has to deal. Clearly, of the four, the paint film is of the greatest interest to the beholder, for it is in fact 'the picture', as generally understood.

From this arrangement the scope of physical and chemical investigations can be gauged. First comes the need for accurate knowledge of the physico-chemical properties of plaster and wood. Secondly, the ground is perhaps composed of 'gesso', a water paint containing lime as its main constituent, and often the seat of an involved system of cracks, which may influence the layer above. Thirdly, the paint film is a most complicated phase, comprising pigment plus binding medium. Fourthly, the varnish film is not an exact chemical entity, and its properties change considerably with time. All these layers react to some extent upon one another, more especially with regard to relative flexibility. Chemical reactions in the paint film sometimes generate fissures akin to geological phenomena on a minute scale.

In general, the paint film may be constructed in a variety of ways. The pigments may be embedded in a previously prepared surface, or they may be powdered with a suitable medium (as in ordinary oil painting), or again they may be applied to a dry surface and afterwards fixed by some kind of spraying.

As in other branches of science, physical methods may be preferable to chemical ones in that no sampling or removal of minute fragments of material is required. When, however, it is necessary to know for certain the composition of a pigment, then it has long been the custom to detach a microscopic amount from some inconspicuous part of a picture (under the rabbet of the frame for example) and to subject it to chemical or spectroscopic analysis. In very favourable cases, observation with a polarizing microscope will give a clue to the nature of a pigment *in situ*, by reference to crystallographic properties, colour and index of refraction. An extremely illuminating method—when conditions allow—is to use a micro-borer, and so to obtain, in the form of a minute cylinder, samples of all the different strata. Microscopical examination of the core, at a magnification of about one hundred diameters, reveals the constituents clearly.

The possibilities of X-ray work are considerable, and at several institutions systematic use is being made of them. The whole process, so far as pictures are concerned, depends for its success upon the particular pigments and technique in question. It is by no means of universal application. Exceedingly thin films of paint, such as

those sometimes used by the Venetians, are frequently too transparent to offer any appreciable resistance, except perhaps to the very softest radiation. However, areas containing much lead or mercury, in the neighbourhood of compounds like the lakes, composed of elements of low atomic weight, make excellent subjects, and a wealth of detail is often revealed. Sometimes the experienced eye can perceive the presence of an outline under the visible paint layer: X-ray photographs supply the objective proof. The uses to which such photographs can be put are several. If it is proposed to remove over-paint, the extent of the original picture left can be determined before any action is taken. Again, a previous version of a composition may be discovered or, as has happened lately, the work of two artists can be distinguished.

It remains now to discuss some external factors which influence the condition of paintings, and to which it is possible to apply scientific methods. For many years there has been an increasing movement for the abolition of the glasses from pictures in the national collections. From the students' point of view such a course would have everything to recommend it. In practice, however, difficulties are encountered. Experiments have shown that the surface of a canvas, if unglazed, is usually cooler than the air of the gallery, and consequently condensation of moisture sets in, forming a thin wet film over the varnish. Dust and smoke particles settle on this film, and create in time a dull, dirty layer, easily removable in some cases, but by no means in all without risk to the varnish. The cure, theoretically, is a complete air-conditioning and filtering plant. Observations in the National Gallery have demonstrated that for every pound of carbonaceous material per million cubic yards of atmosphere in the immediate neighbourhood of the gallery, 0.7 lb. is present within the building. This is an average figure for the interior as a whole, and seems to represent a fairly constant quantity. In any event, there is a strong argument for air-conditioning in museums and galleries if objects of art are to be seen at their best.

Perhaps the greatest need of all, as indicated already, is a closer understanding between the outlook of the student of art history and that of the scientific investigator. Co-operation for practical ends like conservation and protection there must obviously be. But the ultimate aim is a more intimate fusion of the two ways of thinking, such as would lead to the appreciation of a work of art as an object of the profoundest symbolism. Some of the great masters were intellectuals of a high order, as well as supreme craftsmen. To know them better is to broaden our concept of natural philosophy.

Agricultural Products as Raw Materials for Industry*

TO what extent is agriculture likely in the future to supply the raw materials for industry in addition to food and textiles, her main customers to-day? The answer to this question involves a forecast of both demand and supply: whether the nature of the demands will alter, and whether in meeting them materials or manufacturing methods will change fundamentally. Biochemistry and biotechnology are of great significance for the future of industry, but their value will be judged largely by their power to save expenditure of material and energy. For more than a century, organic chemists have been investigating the atomic structure of the products of organic life, and the new weapons, X-rays and electron diffraction, have been of great service.

Although we still know very little of the mechanism used by Nature in synthesizing these complex substances, it is clear that they are built up on comparatively simple models. Starch, cellulose, hemicellulose, and the pectins appear to be built up from hexose units like glucose, though possibly the primary unit is a triose, like glycerin, containing three carbon atoms, since the units $C_3 - C_3$ and $C_3 - C_3 - C_3$ occur frequently in plant products and the transformation $2C_3 = C_6$ presents no difficulty to Nature. Vegetable oils, fats and waxes are built up of long chains from units of six carbon atoms. Essential oils, resin and rubber are built up from the unit C_5H_8 with

a branched carbon skeleton  $C - C - C$, which

may be regarded as their parent substance; and from the same unit the plant can construct the terpenes and diterpenes, which have ring structures. The resins are more complex, containing twenty or more atoms, but of similar type.

Proteins are derived from the union of ammonia with carbon-chain units; amino-acids are formed, and their molecules combine to make long chains, like fibroin, the chief protein constituent of natural silk. Long chains similar to these, but folded into rings, are the structural units of the vegetable proteins found in many seeds and tubers. Many alkaloids also can be regarded as built up in the plant through the medium of amino-acids.

The mode of formation of chlorophyll—the key substance in the living world—is obscure; it presents us with the old problem of the hen and

the egg, for chlorophyll is essential for the synthesis of carbohydrates, but carbohydrates are required to make chlorophyll. Many natural flavouring substances, for example, eugenol, are built up upon a $C_6 - C_3$ skeleton, and this group may be doubled to give constituents of many resins, or with the addition of a C_2 group to give the catechins, found in the tannins, and in anthocyanins, the colouring matter of many plants.

Although Nature synthesizes her complex products from simple units with an ease and certainty that tantalizes the chemist, by elucidating their structure, he has succeeded in synthesizing many of them artificially. Nevertheless Nature has proved to be a cheaper producer than the factory, and is likely to remain so. Many so-called synthetic substances, for example, camphor and ionone (the perfume of violets), are made from vegetable products in which the carbon skeleton has already been formed by the plant, and they are thus the result of chemical processing.

Of greater significance from the point of view of displacement of plant products, is the use of cracked oil gas and natural gas in the United States as starting-points for the manufacture of organic chemicals, and also their production from water gas by catalytic processes, and from calcium carbide made in the electric furnace. Here there is direct competition with the products of the fermentation industry and of wood distillation. Synthetic 'rubber' made from cracked oil gas is another example of this competition. On the other hand, the more detailed knowledge of plant products has led to great developments in their extraction and utilization, for example, the process of fat-hardening, the conversion of molasses into alcohol, glycerin, acetone and other solvents, and the production of furfural from cereal wastes for use as a solvent or as a constituent of plastics. Research has also opened up completely new fields, such as the cellulose products and synthetic resins or plastics, in which agricultural materials like casein, glycerin, soya bean are finding fresh outlets. The possibilities of plastics are great; at present they are handicapped by high cost, moulding powder costing £75 to £100 a ton, and the great pressures required for moulding thermo-plastics are expensive to apply to large articles.

The present percentage utilization of agricultural produce in the world is, on a value basis, roughly: food 86-88, textiles 9-8, and other industries 5-4, so that the consumption by industry is at most only 12-15 per cent of the total production, and

* Based upon the Mather Lecture given by Sir Harold Hartley to the Textile Institute on June 11.

of this textiles account for about two thirds. On this basis it is estimated that the value of farm, field and forest products used in industry now amounts to about one half that of mineral products, that is, to one third of the whole value of industrial raw materials.

The extent to which agricultural materials may replace minerals and metals will depend on physical properties and cost. Some plastics are suitable for replacing metals; the use of synthetic resins as adhesives, and the improvements in the manufacture of laminated wood already make it a successful rival to metal in many fields, for the new products possess such advantages as absence of fatigue, high ratio of strength to weight, and resistance to corrosion, whilst the defects of wood due to local weakness are eliminated by the laminated structure. Rubber is also supplanting metal in fields where its elasticity, freedom from abrasion, and value in reducing noise are required. Laminated wood is finding many applications in building construction owing to its strength, lightness and low cost; and the substitution of nitrocellulose and synthetic resins for the older natural resins, and that of the new solvents and plasticizers for the older and cruder materials of the forest-produced type, all in the main involve the use of processed agricultural products. The cost of producing fermentation alcohol from molasses, at 2d. a gallon, is estimated at 9d. a gallon; and from maize at 2s. a bushel, at 1s. 3d. a gallon; but the cost of petrol at the refinery without tax is 3d. a gallon; its use to-day as motor fuel is only justifiable on strategic grounds, but when petroleum supplies begin to contract, alcohol will be in a better competitive position. There has been a very great development in the use of new packing materials, made of wood, textiles, cellulose, Cellophane, etc., but mineral oils have been replacing vegetable oils for lubrication, although the total consumption of the latter has not declined.

In the United States, the Farm Chemurgic Council is working strenuously to promote the use of American farm products; and the Department of Agriculture, with its numerous associations, is admirably equipped for research and development work in this connexion; as also in the wider field of finding new crops like soya bean, tung oil and southern pine, to replace products now imported. Success will depend on the co-operation of industry in providing factories for processing the raw materials and the research necessary to find new and cheaper methods of using them. The utilization of farm wastes and by-products is being investigated; already cull citrus fruits in California are being processed for producing citric acid, citrus oils and pectin, but an economic method for using waste farm cellulose for paper, strawboard,

insulating material or packing has yet to be found. Within the last decade, the soya bean has become a major crop in the United States. One ton of it yields about 250 lb. of oil and 1,600 lb. of meal. The oil is used in edible products and in making paints, enamels, varnishes, linoleum, soap, glycerol and printing inks. The meal is mainly used in foodstuffs, but a good deal goes to the manufacture of protein glues, paper sizes, washable wall-papers and protein plastics. Mr. Henry Ford has been one of the pioneers of this new crop. It is estimated that the annual output of a million Ford cars involves the consumption of the following quantities of farm produce: cotton 80 million lb., maize 500,000 bushels, linseed oil 2.4 million lb., molasses 2.5 million gals., wool 3.2 million lb., leather 1.5 million sq. ft., hogs 20,000 (to supply lard for lubricants, oleic acid and bristles for brushes), mohair 350,000 lb., and soya bean oil 2 million lb. (for making enamel).

The discovery of new uses for established crops is well exemplified by research on cotton, which has disclosed the effect of fibre fineness on the strength of cotton yarns. Extensive breeding and selection are showing how to improve this characteristic in American cottons. Strength and durability are needed in cotton used for making bags and bagging, and a fresh outlet here is the development of duplex open and close-mesh fabric bags for packing fruits and vegetables, millions of which have been sold. The use of cotton fabric for reinforcing tarred roads has been investigated and with seeming success. After the road bed has been levelled and primed with tar, the cotton fabric is laid down and then covered with alternate dressings of asphalt, road metal and chips, which are consolidated with a heavy roller. Strenuous efforts are being made to find new uses for maize. In the Middle West about 7 per cent of the maize crop is processed for industrial purposes, the main products being starch, dextrin, corn syrup, dextrine, corn oil and cake. Finally, sugar or starch derived from second-grade maize or other grain, sugar-beet, and molasses is being converted into industrial solvents.

The energy and skill with which all these investigations are being pursued is beyond praise. The answer to the question posed in the first sentence cannot be definite. The use of carbon compounds is certainly being extended, and perhaps we are approaching a cellulose-plastic age. But the chemist cannot vie with Nature in the cheap production of complex organic molecules: and the future lies in closer association between them. Such a development of the use of agricultural products would be most fortunate in view of the gradual exhaustion of our capital assets, coal and oil.

New Zealand Fish Oils

By F. B. Shorland

ALTHOUGH the fish life of New Zealand waters offers many interesting and unusual features, the study of the fish oils has, until quite recently, been practically neglected. The earlier work included an analysis of sting-ray liver oil by Donovan¹ and more extensive researches on the food values of New Zealand fish initiated by Malcolm in 1920. During the course of these investigations the oil content of the flesh from various fish was examined^{2,3} and the fats of red

A. australis, have received considerable attention. It was found that the body oil (comprising so much as 20 per cent of the total weight of the fish) had a vitamin A potency approaching that of cod liver oil, while the traces of oil in the liver were extremely rich in this vitamin^{2,3}. McIntosh and Shorland⁴ established a general similarity between the composition of the component fatty acids of *A. aucklandii* and that of typical freshwater fats of the northern hemisphere analysed by Lovern¹⁰,

CHARACTERISTICS OF SOME NEW ZEALAND AND OTHER FISH LIVER OILS

Species	Body weight	Liver weight	% Oil	Iodine value	Saponification value	% Unsat. matter	% Vitamin A (Elem. 328 mg) 10	
New Zealand	Ling (<i>Gerypterius blacodes</i>)	20 lb.	1 lb 7 oz	35	137-153	183-189	2-4	0.6-0.7 (usually)
	English hake (<i>Merluccius gayi</i>)	18 lb	1 lb. 6 oz	35	132-143	185-187	2-4	0.3-0.8
	Groper (<i>Polyprion oxygeneios</i>)	10 lb.	6 oz	5-10 (usually)	82-122	176-197	3-15	0.5-5.0
	Bass (<i>Polyprion americanus</i>)	somewhat heavier than groper	8 oz.	5-10	78-131	175-191	4-16	1.0-4.5
North Sea	Cod* (<i>Gadus morhua</i>)	17 lb.	14 oz	60-70	140-180	180-190	1	0.01-0.05
	Halibut* (<i>Hippoglossus vulgaris</i>)	60 lb	1 lb	20	111-171	150-175	8-22	0.2-1.0 (usually 1-1.5)
	Hake (<i>Merluccius merluccius</i>)	—	—	—	140-159	184-186	0.9-1.7	similar to cod liver oil
Chilean	¹⁴ (<i>Merluccius gayi</i>)	—	—	—	185	176	2.0	similar to cod liver oil
	¹⁴ <i>Gerypterius blacodes</i> and <i>G. chilensis</i>	—	—	—	160	188	0.2	somewhat stronger than cod liver oil.

* Typical values from the results of various investigations.

cod (*Physiculus bachus*) in relation to its food were studied. The fat content was less in winter than in summer, indicating a depletion of reserves during the scanty winter feeding⁴. Although tarakihi (*Dactylopagrus macropterus*) flesh was found⁵ to contain appreciable amounts of vitamin A, none could be detected either in the ether extract of this flesh or in the ether extracts from the flesh and liver of red cod⁴.

Denz and Shorland⁷ discovered in 1934 that the larger edible fish of Cook Strait, including ling, English hake and in particular groper and bass, yielded liver oils of much higher vitamin A potency than had generally been recorded in the case of North Sea fish. In contrast with the fish which had hitherto been examined by other investigators, the vitamin A content of ling liver was not found to exhibit any marked seasonal variation⁸.

Lately, New Zealand freshwater eels, of which there are two species, *Anguilla aucklandii* and

thus confirming the difference between the marine and freshwater types of fat. An examination of the C₁₈ unsaturated acids showed the presence of oleic and stearidonic acids. Neither linoleic nor linolenic acid could, however, be detected⁹. Edisbury, Lovern and Morton¹¹ showed that the ratio of non-liver vitamin A to liver vitamin A of *A. aucklandii* tended to increase with age, while the increased vitamin content of the body oil in the older fish was correlated with the oil content of the tissue.

In many instances, fish oils of high vitamin A potency are also good sources of vitamin D. Cunningham¹² reported vitamin D values of 2,250 and 500 for groper and ling liver oils respectively, as compared with 100 international units per gram for good cod liver oil. Skate (*Raja nasuta*) liver oil and the body oil of freshwater eel gave, respectively, the lower values of 15 and 47.

The deep-sea fishing industry of Cook Strait, which provides the commercial liver oils, is rather

limited on account of the small area of the banks. About 8,000 cwt. of groper and 2,000-4,000 cwt. of ling are caught annually, together with smaller quantities of English hake and bass. In other large centres such as Auckland, smaller fish, including snapper, tarakihi and flounders, predominate, and although some of these yield a small proportion of vitamin-rich oil the livers invariably weigh less than 2 oz.

Cook Strait elasmobranch liver oils are not rich in vitamin A. Skate (*Raja nasuta*) liver oil, for example, is less potent than cod liver oil. Oils from individual livers are sometimes exceptionally potent. That from a bass contained 10 per cent vitamin A, while a swordfish from North Auckland yielded a liver oil with some 14 per cent of this vitamin.

An examination of the properties of the liver oils given in the accompanying table for the same or similar species inhabiting different waters suggests that the composition and vitamin A content are sometimes determined more by environment than by biological considerations of species.

Observations on the properties of groper liver oils, which will be published in detail elsewhere, show that the winter oils, especially during July and August, approach the upper limit given in the table as regards vitamin A content, iodine value, and percentage of unsaponifiable matter. During the intensive feeding of October and November, these values approach the lower limit and the livers become softer owing to the infiltration of fat, which in some instances increases the oil content to 20 per cent of the liver weight. The oil from *Sardinia neopilcharda*, a source of food at this time, gave no reaction for vitamin A. Seasonal changes in the properties of groper liver oils thus appear to be associated with alternate intensive feeding and relative starvation. The North Sea halibut affords an interesting contrast with groper in that the potency of the liver oil is lowest in winter but rises to a maximum during the seasonal increase of diatomaceous food in the spring¹. Winter groper liver oil is exceptional in containing as much as 20 per cent phosphatide. An analysis of the component fatty acids of these oils is being made under the direction of Prof. T. P. Hilditch, of the University of Liverpool. Examination of other fat depots including the roe, head and stomach failed to reveal the presence of vitamin A except in the stomach oil.

Further work on ling liver oil at present in progress substantiates the lack of marked seasonal variation of vitamin A content or in yield of oil as determined by ether extraction. Of the total fat present in the fish, more than 96 per cent is concentrated in the liver, and during spawning

less than 0.5 per cent of this fat is transferred to the roe. The ether extract from the ova gave no Carr-Price test, while that from the stomach showed a value of 800. Lack of seasonal variation in the vitamin A content during spawning seems to be explained by the fact that the production of ova requires an insignificant drain on the liver oil. Both cod and halibut appear to derive their vitamin-rich liver oils from food relatively deficient in this vitamin by a process of intensive storage^{12,14}. In these circumstances, it is not surprising to find that the livers from the older fish contain a higher concentration of vitamin A^{15,17}. In the case of Cook Strait ling, however, the chief food is whiptail^{18,19}, which is rich in vitamin A (a specimen taken from a ling stomach, for example, yielded an oil giving a Carr-Price value of 75), so that relatively little storage is necessary to produce a vitamin-rich liver. In confirmation of this observation, the larger livers from the older fish have not been found to yield a more potent oil than the smaller livers.

Ling liver oil is distinguished from typical liver oils of the North Sea by the higher content of C₁, unsaturated acids (35-40 per cent as compared with 27-30 per cent) and the low proportions of palmitoleic acid (7-10 per cent as compared with 15-18 per cent). The ether extract from the roe contains about 56 per cent phosphatide. As in the case of animal fats, the phosphatide fraction is richer in C₁ and C₂, highly unsaturated acids than the glyceride fraction. The relative proportions of C₁, C₂, acids in the liver, viscera, roe glyceride and roe phosphatide may be given approximately as 35, 45, 40 and 50 per cent respectively.

I wish to record my sincere appreciation and thanks to the directors of the British Drug Houses, Ltd., London, for generously placing their analytical laboratories at my disposal. Thanks are also due to Mr. T. T. Cooking of that laboratory for valuable advice, to Prof. T. P. Hilditch for his continued interest and to the Department of Scientific and Industrial Research, New Zealand, for a scholarship.

Obituary Notices

Dr. J. W. Capstick

JOHN WALTON CAPSTICK, who took a prominent part in the work of the Cavendish Laboratory from 1891 to 1898, and in the administration of Trinity College from 1895 until 1910, was born at Lancaster on August 31, 1858, and educated at the 'Friends School' in that town. In 1880 he went to Owens College, Manchester, which was then a part of Victoria University; he won at Owens the senior Dalton mathematical scholarship in 1882 and took first class honours in mathematics at the examination for the B.A. degree at the University of London in 1883. He then took a teaching post in the University of Dundee, saved some money, and entered Trinity College, Cambridge, as a sub-sizar in 1888. He was elected to a sizarship in 1889 and to a scholarship in 1890. He took a first class in Part I of the Natural Sciences Tripos in 1890, and one in Part II, with distinction in both physics and chemistry, in 1891.

In that year, Capstick began original research at the Cavendish Laboratory on the values of the ratio of the specific heats in gaseous compounds of various types. He was a very good experimenter, a skilful manipulator, and very persevering, and was never content until he always got consistent results. These researches, which gave valuable additions to our knowledge, were published in two papers in the *Philosophical Transactions of the Royal Society* for 1894 and 1895. They had much to do with his election to the Courts Trotter scholarship in 1892 and to a Trinity fellowship in 1893. His next research was on the relation between the 'cathode fall of potential' in compound gases of different types; he was, however, unable to get consistent results; we know now that a mere trace of impurity produces a great effect on the cathode fall, and to remove these traces requires methods of producing high vacua which had not been invented at that time.

In 1895 Capstick was appointed lecturer in natural sciences in Trinity College in succession to Glazebrook, who had been appointed senior bursar; he gave lectures at the laboratory to candidates for the Natural Sciences Tripos, and in 1898 he took over the lectures for medical students which Glazebrook had given for many years. He was appointed to the very arduous post of junior bursar at Trinity College in 1910, and though he still continued to give some lectures at the Laboratory he had no time for research. He was a very successful junior bursar; he liked the work and did it very well.

Capstick had an exceptionally wide range of interests and activities. He took an interest in motoring from its very early stages, and kept in touch with its development. Thus, he was one of the first to drive a motor-tricycle, then he tried a steam car; he must have tried about half a dozen types of cars in his time and was always convinced that the new one was much better than the last. He turned his skill as a driver to good purpose during the Great War; he volunteered for the Red Cross, and for a

year drove a motor ambulance for the French Army. He was always anxious to help other people. When at the very beginning of the War the Cloisters in Nevilles Court in Trinity College were used for a military hospital, he visited the hospital regularly and often after talking to a patient he would take his photograph and give him copies to send home to his friends. He was an expert photographer, but it required more than photography to think of doing a deed like this.

Capstick had a great love for music, and it was one of the chief interests of his life. For many years he took the leading part in teaching acoustics to the candidates for musical degrees. He was not merely a good lecturer on music but was also a good musician and a good player of that exceedingly difficult instrument the French horn. For years a regular attendant and valued member of the orchestra of the Cambridge University Musical Society.

Capstick's health broke down suddenly about five years ago, and for the rest of his days he had to live the life of an invalid; he died at his house in Cambridge on April 27. His old friends cherish the memory of the help, the kindness and the good companionship they received from him. J. J. T.

Prof. S. Pennington

PROF. SYDNEY PENNINGTON, who died at Newport, Salop, on July 19, was born in 1869 and received his early education at Giggleswick School under the headmastership of the Rev. George Style. After leaving school in 1888 he had four years experience of practical agriculture in Shropshire. The next three years he spent in study at the Royal (Dick) Veterinary College, Edinburgh, and the Royal Veterinary College, London, obtaining the diploma of M.R.C.V.S. in 1895. After this he again returned to farming until 1902, when he decided to enter upon another course of study. Consequently, at an age considerably beyond that at which men now commence their academic career, and with a very thorough knowledge of farming practice, he proceeded to the University of Edinburgh, whence he graduated with the degree of B.Sc. in Agriculture in 1905. His first teaching appointment was as lecturer in veterinary hygiene in the School of Agriculture at Ghizeh in Egypt. In 1908 he returned home, and was in that year appointed lecturer in agriculture at what was then University College, Reading. In recognition of his work he was elected the first professor of agriculture at Reading in 1920. After twenty-five years service to the University of Reading, he retired in 1933, and was accorded the title of emeritus professor.

Pennington will be remembered best as a great teacher by the many agricultural students who passed through his classes. He was himself so full of enthusiasm for his subject that he readily infected others and especially young minds. This was even more marked in his farm classes, where he drew so largely from his personal experiences. He had the secret

of making his students feel they were listening to one who spoke from living contact with a living world. In addition to his teaching duties, Prof. Pennington had charge of the University Farm. When he commenced his work at Reading in 1908 he set himself the task of grading up a herd of dairy shorthorn cattle that would be eligible for registration in Coates' herd book, and at the same time of establishing a herd of cows on the University Farm free from tuberculosis and of good milking type. This he accomplished several years before his retirement, and the herd remains as a record of achievement on the present University Farm. The herd of dairy shorthorns at the National Institute for Research in Dairying was founded largely on cattle of Pennington's breeding.

Though neither an orator nor debater, Prof. Pennington spoke with a sincerity of conviction and a directness of purpose that commanded attention. He loved what was best in literature and art, and gathered together a surprising amount of knowledge and information on many and varied subjects. He was absolutely devoid of pretentiousness or seeking after effect. Pennington carried into everyday life a dignity of thought and conduct that unconsciously raised the tone of those about him.

J. S. L. WALDIE.

Count Robert de Montessus de Ballore

ROBERT FERNAND BERNARD DE MONTESSUS DE BALLORE, whose death occurred towards the end of 1936, was born at Lyons on May 20, 1870. He belonged to one of the oldest families of Burgundy. His mother was a great-granddaughter of Philibert de Commerson, the botanist of the Bougainville expedition, his uncle Ferdinand de Montessus was known as an ornithologist, and his elder brother Fernand was a distinguished seismologist who founded an observatory at Santiago in Chile. For a time Robert de Montessus contemplated a military career, but in his late twenties he made up his mind that such a life was incompatible with a streak of independence in his character, and he began to study mathematics at the Sorbonne. In 1903, while still preparing a dissertation for his doctorate, he was invited to Lille by his friend Robert d'Adhémar, himself a distinguished mathematician, and there he was appointed professor of general mathematics in the Faculty of Science.

Robert de Montessus worked in many fields. Algebra owes to him a fundamental simplification in the use of Sturm's theorem, based on the method of successive approximations; his process is one for evaluating, to an arbitrary degree of accuracy, the real roots of numerical equations, transcendental as well as algebraic. The theory of elliptic functions attracted his attention, and he was stimulated by Halphen's pioneering work to obtain beautiful theorems on the representation, the singularities, and the classification, of algebraic skew curves; he studied carefully the twisted quartic of the first kind, that is, the curve of intersection of two quadrics, showing in detail as Halphen had shown in general terms that the current co-ordinates on this curve are expressible as elliptic functions of a single parameter.

In an important memoir on algebraic continued fractions, which was crowned by the Academy of Sciences, de Montessus presented a body of results constituting great advances in this difficult theory. Starting from a certain fraction which is convergent throughout the whole plane, except possibly on the rectilinear segment joining two points if the function represented by the fraction has two singularities, he deduced that analytic continuation by means of a continued fraction is not impeded by poles, or by algebraic or logarithmic singularities.

In his later years, de Montessus devoted much attention to the theory of probability, which he proposed to found on Bernoulli's theorem, regarded as an experimental fact. He tried also to find a satisfactory theory of correlation which should be applicable when the number of observations is small, and he developed some ingenious ideas on weighted probabilities.

About twenty years ago, de Montessus undertook the publication of the "Index Generalis", an annual reference work now well known throughout the scientific world and of inestimable value to every investigator. It is hard to conjecture the number of practical difficulties which de Montessus had to overcome in organizing this immense mass of data on the universities and learned societies of the world; the scientific qualities of which he had given evidence elsewhere came to his aid here.

In 1931, during a mission to Central Europe on behalf of the French Government, de Montessus gave courses of lectures on various branches of mathematics in Warsaw, Cracow, Lwow, Budapest, Vienna and other universities.

Robert de Montessus, has left the memory of a modest and conscientious scholar, an upright man, and a firm friend.

HENRI VILLAT.

We are indebted to Mr. E. Mather for the information that the early training of his father, Prof. Mather, was that of an engineer, not that of a carpenter as stated in the obituary notice in *NATURE* of July 17. Prof. Mather came from a family of engineers. We also learn that, during the Great War, Prof. Mather devoted much time to the invention and development of a device for giving warning of the approach of enemy aircraft.

We regret to announce the following deaths:

Prof. P. E. Brown, head of the Department of Agronomy in the Iowa State College, known for his work in soil science, on July 8, aged fifty-one years.

Lieut.-Colonel E. G. Ffrench, known for his researches in tropical medicine, especially dermatology, on July 25.

Prof. D. M. Lewis, emeritus professor of physics in the University College of Wales, Aberystwyth, on July 28, aged eighty-five years.

Prof. J. Wilhelm Michaelsen, head of the Department of Natural History in the Hamburg Museum, an authority on the Oligochaeta, on February 18, aged seventy-six years.

News and Views

Prof. R. A. Sampson, F.R.S.

THE retirement of Prof. R. A. Sampson from the position of Astronomer Royal for Scotland has been recently announced, and will shortly take effect. He has held this office, which is associated with the professorship of astronomy in the University of Edinburgh, since 1910 when he succeeded Sir Frank Dyson on the appointment of the latter as Astronomer Royal at Greenwich. Prof. Sampson's career has been long, varied and distinguished. His earlier years were spent in posts mainly mathematical, and it was only comparatively late in life that he was able to devote all his time, during the twenty-seven years at Edinburgh, to the pursuit of astronomy. But much of his astronomical work had already been done in the earlier period. Happily, this is not the occasion—may it be long distant—when it is necessary to give biographical details or to assess the value of scientific achievements. But it is interesting to recall that Prof. Sampson was the first product of the Isaac Newton studentships (1891–3), then lately founded by Mr. F. McClean, for he gained this prize a year after his election to a fellowship at St. John's College, Cambridge, where his mathematical career had been eminently successful. Between 1893 and 1910 he held a mathematical professorship first at the Durham College of Science, Newcastle-upon-Tyne, and after 1896 at the University of Durham, where (after 1908) he was also professor of astronomy.

PROF. SAMPSON'S first work on a large scale was the editing of the astronomical papers of J. C. Adams, which demanded critical qualities of no common kind. But the work with which Sampson's name will always be associated is that on the four great satellites of Jupiter. This fell into three main phases, all involving immense labour. The first was the reduction of the photometric observations of eclipses of the satellites made at Harvard, the second was the subsequent production of "Tables of Jupiter's Four Great Satellites". These were carried out at Durham. The third phase was a memoir (1921) containing the theory of the four great satellites of Jupiter. The whole of this work constitutes a monument of industry and power. Much else of Prof. Sampson's work in the domain of optics, solar physics, time-keeping and other subjects are of value, but need no more than mention here. The recent history of the Edinburgh Observatory, with the provision of a 36-in. reflector, is too familiar to call for description. Born in 1866, Prof. Sampson has seen the revolutionary change which has influenced the development of the science to which his life's work has been devoted. A sincere hope may be expressed that he will for many years to come have the happiness of seeing the progress of astronomy continue in the manner he has himself so clearly appreciated. (See also p. 229.)

Prof. J. H. Burn

PROF. J. H. BURN has been appointed to the chair of pharmacology in the University of Oxford. At Cambridge, Burn was president of the Union. After serving as a temporary lieutenant in the Royal Engineers he obtained his M.B. degree in 1920, and joined the staff of the National Institute for Medical Research under Sir Henry Dale. In 1925, he was appointed director of the Pharmacological Department of the College of the Pharmaceutical Society of Great Britain. Later he became Dean of the College, and was given the title of professor of pharmacology in the University of London. During the last twelve years he has been responsible for thousands of pharmacological tests carried out on behalf of manufacturing firms. This work has given him an unrivalled experience of the fundamental scientific work upon which a great industry depends. Through his own work, and that of his colleagues, he has devised new tests and improved old ones for a large number of hormones, vitamins, synthetic chemotherapeutic agents, and plant extracts. Besides all this, he has found time to do fundamental pharmacological work, particularly on vasoconstrictor and vasodilator nerves, and to write several books. He has built up a department which is not only famous for its contributions to knowledge, but has also had a direct effect in raising the standard of pharmaceutical products in Great Britain. With the appointment of Prof. Burn, Oxford should look forward to a period of great activity in her Department of Pharmacology.

Dr. H. S. Harrison

IN October next, Dr. H. S. Harrison will retire from the staff of the Horniman Museum, Forest Hill, London, S.E., after thirty-three years service. Dr. Harrison was appointed curator in succession to R. Quick in 1904, not long after the Museum had been transferred to the London County Council by the late Mr. E. J. Horniman. Dr. Harrison re-organized and extended the collections, and the Museum became, and continued to be, under his direction an important centre for lectures on subjects illustrated in the collections, more especially in connexion with the County Council's scheme of lectures for the teachers of the London schools. The value of the collections for the general public was much enhanced by the series of small popular guides written by Dr. Harrison, more especially those on technology, of which "From Stone to Steel" is now in its third edition. Dr. Harrison was formerly honorary secretary of the Royal Anthropological Institute, edited its *Journal* for some years after he relinquished that office, and was president of the Institute in 1935–37. In 1930 he presided over the Anthropological Section at the Bristol meeting of the British Association, when his presidential address, which dealt with the diffusion

of culture, aroused no little interest both in Great Britain and, more especially, in the United States by his well-balanced handling of the subject. Dr. Harrison will be succeeded at the Horniman Museum by Dr. L. W. G. Malcolm, who since 1935 had been a member of the inspectorate of the London County Council, and has been engaged in organizing arrangements for the further utilization of the resources of the museum collections of London by the pupils of London schools as part of the educational curriculum. Dr. Malcolm, on coming to England from Australia, was trained as an anthropologist at Cambridge by Dr. Haddon and in Germany. He was formerly curator of the ethnographical collections in the Bristol Municipal Museum and later conservator of the Wellcome Historical Medical Museum.

British Pharmaceutical Conference at Liverpool

THE seventy-fourth British Pharmaceutical Conference was held on July 26-30 at Liverpool, this being the fourth occasion upon which Liverpool has given hospitality to the Conference. Mr. T. E. Leecher delivered his presidential address entitled "Pharmacy Today—Its Responsibilities" the main theme of which was the contrast between the important contribution made by pharmaceutical research to the national well-being and the lack of official recognition of this service. Many painstaking chemical, pharmaceutical and biological investigations, said Mr. Leecher, have resulted in placing the treatment of disease increasingly on a scientific basis by the discovery of specific remedies which remove the cause of disease rather than alleviate its symptoms and, of almost equal importance, have, where necessary, enabled these remedies to be taken in a form which does not cause the patient to rebel against them. In view of such achievements, it is surprising that the pharmacist has not received the recognition which his work and responsibilities deserve and which his Continental confrère enjoys. The present system of allowing anyone to handle the majority of drugs and medicines on payment of a five-shilling licence annually encourages the exploitation of the public by the distribution of 'cure-alls' without the slightest guarantee of any knowledge of their properties on the part of the vendor. The official attitude in its latest form is seen in the report of the Select Committee on Medicine Stamp Duties, which recommends what is in effect a sales tax on medicines if claimed to be beneficial to health. It is almost unbelievable that a body of public men should suggest that the State is justified in taxing medical substances used in ill-health.

Julaber's Grave, Kent

THE mound or barrow known as Julaber's Grave or Julliebarrie, at Chilham, near Canterbury, has long been an object of interest to archaeologists and others, mainly perhaps on account of the lack of precise evidence of its character and age. It is thought to be neolithic, dating from about 2000 B.C. Its excavation has been undertaken by Mr. R. F. Jessup,

the author of the volume on Kent in the County Archaeology series, on behalf of Sir Edmund Davis of Chilham Castle. The barrow is 144 ft. long, by 45 ft. wide. In the initial operations, which were carried out last year, the course was traced of the ditch running round the mound, from which its material was taken. In the investigations of the present season, a longitudinal section has been cut, following the ditch, which has revealed the construction of the barrow above the original chalk surface. This shows a darker section where the original turves form a core and a loose rubble of chalk from the ditch. A particularly interesting find is recorded (*The Times*, July 31). This is a large circular burial in the side of the mound, probably of Roman date. It shows the cutting through the neolithic layer and the careful replacement of the mixed soil. This is held to support the view that the barrow is the burial place of Laberius Durus, one of Caesar's generals of the second invasion, of whose name, "Julaber" is thought to be a local corruption. Another interesting find is that of three skeletons at the edge of the ditch at the south end of the mound, three feet below the surface. These have been ascribed to Romans of the third century of our era. They are the remains of a large, well-developed man, a child and a girl. The child's bones were extremely fragile and disintegrated at once, but the small drinking vessel, a platter of rough coarse black ware, and the fibula, which had held the shroud together, were recovered. The girl's remains were fairly well preserved, but those of the man were in an excellent state of preservation.

Angmering Roman Villa

AN appeal is issued for funds for the excavation of the extensive Roman villa site near the old village of Angmering, Sussex. The site is situated in the flat meadows which lie between the downs and the sea, beside a Roman road, still to be traced with probability as a farm track between Lyminster and Poling, and as the footpath from Poling to Angmering across the Black Ditch. The site first attracted the attention of archaeologists in 1819, when a Roman bath was discovered, with hypocaust, sudarium and sewers. This bath was rediscovered at the beginning of the present year, and the whole bath building is now being uncovered by Mr. R. C. Sherrif and the Littlehampton Archaeological Society, with the co-operation of the Sussex Archaeological Society, under the direction of Miss Leslie Scott with Dr. R. E. Mortimer Wheeler acting as advisory director. The bath building comprises a dozen or more rooms, some with hypocausts, grouped around a cold-water tank. The building appears to stand by itself, surrounded by a beaten chalk causeway, flanked on the west side by a ditch. It was built in the latter part of the first century, and is interesting both on account of its early date and for the richness of its internal decoration. Beside the usual painted wall plaster and window glass, common on such sites, there is evidence that some walls were faced with slabs of different coloured stones. The bath building was destroyed in the middle of the second century;

out whether it was rebuilt can only be decided by excavation. The villa appears to lie to the west. With so rich a bath house, it should be a fine example of an early Romano-British country house. The cost of the complete excavation will be £500, of which £150 is required to finish the present season's work. The appeal is issued by a Committee of which Mr. E. W. Hulme is the chairman and Mr. E. J. F. Hearne the hon. secretary. Donations should be addressed to Mr. D. Crawford, Hon. Treasurer, Angmering Roman Villa Excavation Fund, Barclay's Bank, Littlehampton, Sussex.

Roman Leicester

Excavations, which have now been resumed on the Jewry Wall site at Leicester, have brought to light a remarkable example of the Roman bath, where the Roman forum and basilica were discovered by previous excavations (*The Times*, July 31). The bath is situated in the middle of the open space in the centre of the forum. It is probable that this bath was the largest built in Britain by the Romans. It is on an enormous scale, and comparable to the Imperial baths at Rome. It has one suite for men and one for women, with hot, cold and warm rooms. Miss Kathleen Kenyon, who is again in charge of the excavation, is of the opinion that it was built at the beginning of the fourth century A.D. about two hundred years after the erection of the forum.

Mass-Observation

At a meeting of the Engineers' Study Group on Economics on July 23, Mr. Charles Madge, joint organizer of "Mass-Observation" (6 Grotes Buildings, Blackheath, London, S.E.3), gave a preliminary account of some of the results already obtained. "Mass-Observation" was begun at the end of 1936 to find out more about everybody's everyday normal life and habits. There are now voluntary observers at work all over the world, and special surveys have been made of the life of the community on certain days. It was found that observers' references to people fall mainly into three categories: (a) people one knows or one has met already; (b) strangers—people one meets in the street, or for the first time; (c) celebrities, one hears of, or reads about in the newspapers. Most reports dealt with the unusual happenings of the day, and the observers had, generally, to be reminded not to overlook the routine happenings. Mr. Madge pointed out that the movement uses both trained and untrained observers, and he stressed the great value of having so many observers who have voluntarily offered to supply information of their immediate surroundings. Although many of them are untrained for this special work, nevertheless, much material of value is being gathered. The chairman (Mr. Alexander Farquharson, secretary of the Institute of Sociology) remarked on the useful relationship that the work carried out by "Mass-Observation" had to that of the sociologist, in supplying raw material not always easily obtainable.

Utilization of Leisure

At a subsequent meeting of the Engineers' Study Group on July 30, Mr. M. M. Bruce, secretary of the London Council of Social Service (7 Bayley Street, W.C.2) outlined the results of a survey undertaken in co-operation with other bodies (L.C.C. Education Department, Y.M.C.A., Young Communist League, trade unions, co-operative societies, Workers Educational Association) to determine how young people between the ages of fourteen and twenty-five years spend their leisure. Some 5,000 answers—an admittedly insufficient sample—were received, which gave an indication of the wide variety of interests. The largest proportion of predilections expressed for any one type of recreation goes, with young men to outdoor sports (11 per cent) and with girls to dancing (30 per cent). The influence of the cinema was very evident in the choice of girls' fashions and hair-dressing styles. A tendency away from organized sports (football, etc.) towards the more individual type (rambles) was also noticeable. The investigation is being continued by a smaller committee, which is looking further into these particular aspects. The survey acquires a particular significance in view of the fact that the Government will, in the autumn, begin a campaign to improve both the physical and the mental abilities of the people of Great Britain.

Annual Report of the Astronomer Royal for Scotland

THE forty-seventh annual report of the Astronomer Royal for Scotland records the work done at the Royal Observatory, Edinburgh, for the year ending March 31, 1937. The daily time service for the city of Edinburgh was maintained without change. The transit circle was used exclusively to determine time. An apparatus installed during the year by H.M. Office of Works enables the mains supply to be used as the electrical power maintaining the winding of the clocks. Provision is made automatically for a temporary breakdown in the mains supply, by means of a secondary battery which is kept fully charged by a trickle from the mains. The 6-inch photo-visual refractor has been fitted with a synchronous drive. The solar spectroscope is being used to obtain spectra of the east and west limbs of the sun's disk to determine the solar rotation from the measured Doppler effect. The seismograph provides daily records which are available to other workers in this field. Observations with the 36-inch reflector were interrupted in order to have the great mirror aluminized by a reputable firm. Unfortunately the aluminium coating was not a success, and the mirror was then resilvered at the Observatory. A number of plates were taken with the 10-inch triplet as part of a programme for a search for variable stars near the Selected Areas centred around declination $+75^\circ$ and $+60^\circ$, the plates being examined with a blink comparator. Among the meteorological observations, it may be noted that the maximum shade temperature was 75°F. on August 28 and the minimum of 24°F. on December 7 and February 11. The deep rock thermometers at a depth of 250 inches on Calton Hill gave a minimum temperature on June 8 of 46.3°

and a maximum of 48.3° on December 14, thus showing, as usual, a greatly reduced annual amplitude and almost a complete reversal of seasons at this depth. (See also p. 227.)

The Treub Foundation of Buitenzorg, Java

DR. K. W. DAMMERMAN, director of the Botanic Gardens, Buitenzorg, has sent us a copy of the first report of the Treub Foundation (Treub-Stichting), which was established at the end of last year for the administration and application of the Treub Fund collected in Netherlands India. When, in 1933, the Government of Netherlands India had, for reasons of economy, to make substantial reductions in the grants to the biological establishments at Buitenzorg, a committee was formed to collect donations for this Fund; and the Government gave permission for any sums received from the sale of surplus plants to be added to the Fund. The Treub Foundation has now been legally constituted to take over and administer this Fund.

THE object of the Foundation is to co-operate in maintaining, and, if possible, in extending the scope of, the scientific institutions united under the name of the 'Government Botanic Gardens', namely, the Botanic Gardens at Buitenzorg and Tjibodas, the Treub Laboratory, the Herbarium, and the Zoological Museum and Laboratory at Buitenzorg, and the Marine Investigation Laboratory at Batavia. The Foundation distinguishes donors, patrons, subscribers and corresponding members. Donors are corporations which contribute one sum of at least Fl. 1,000 and persons who contribute one sum of at least Fl. 500; and patrons those who contribute one sum of at least Fl. 100; subscribers contribute at least Fl. 10 annually. Persons who, because of their interest in the Government Botanic Gardens or in scientific research in the Dutch East Indies, are appointed corresponding members will not be obliged to pay any subscription, but, in their own countries, will look after the interests of the Buitenzorg Institutions in co-operation and in concert with the Foundation. The chairman of the Foundation is Mr. J. H. B. Kuneman, member of the Council of Netherlands India; the secretary is the director of the Government Botanic Gardens, and the treasurer, the president-director of the Java Bank. The capital of the Foundation amounted to about Fl. 20,000 on December 31, 1936. Sir Arthur Hill, director of the Royal Botanic Gardens, Kew, has accepted an invitation to act as a corresponding member of the Foundation in Great Britain, and Dr. David Fairchild, Prof. Elmer D. Merrill and Dr. Thomas Barbour have been appointed corresponding members in the United States.

Phenology of 1936

THE Phenological Report for 1936, recently issued by the Royal Meteorological Society, contains the usual mass of statistics, maps, graphs, etc. of the relations between fauna, flora and the weather. It is the forty-sixth report, compiled mainly by Ivan D. Margary, from 477 reporters. The year was remark-

able for its sunlessness generally, for wetness in England and Wales, and a cool winter, so that plants generally flowered late—all in the Midlands, nearly all England, south-east, south-west, and south Ireland, but were earlier in Scotland, especially the west. Insects nearly all appeared late in England, and save for Scotland, spring migrants were generally late because of the cool April; the autumn migrants were mostly early in moving. As in 1934, the lesser celandine was very late, but by early April vegetation had made up the lost ground; late frosts damaged potatoes, beans and most tender growths; fungi were scarce after August, although flowers were especially fine in the dry, sunny late summer and autumn; trees often remained green late, and wind, more often than frost, caused the leaf-fall. A considerable amount of second flowering was noted in autumn on elder, laburnum, dog-rose and apple. Wild fruits did not do so well as cultivated ones, where bumper crops of apples, plums and raspberries were obtained. Garden crops did good, cereals bad, and hay was ruined by rain. After a record early wave of migrants in March, the long April frost caused a marked hold-up until the sunny third week. Bird song was less in the May drought and cold early June; redwings and fieldfares were scarce in the mild winter. An increase in red squirrels was noted in south-west England; but grey squirrels hold their own in the south-east.

An Extra Receiver for the Telephone

BEFORE the introduction of the modern form of hand micro-telephone instrument and before thermionic amplifiers were introduced on trunk telephone lines, the extra receiver was considered a useful means of improving reception. In modern times the popularity of this receiver has greatly declined. At first sight it would look as if when listening with both ears to a long distance call or when in a noisy room it would be a great improvement; but this is rarely the case owing to what is called side-tone, that is, the reproduction by the receiver of room-noise falling on the microphone at the same station. It is far more difficult to sort out the wanted from the unwanted sounds when both are entering both ears, than when one ear alone is used. In the Engineering Supplement to the *Siemens Magazine* of April a new type of the extra receiver is described. It is pointed out that in certain circumstances it is very useful to have an additional receiver. It enables a third person to listen to the conversation and, if necessary, make notes. As this facility is only required occasionally, and if this receiver were always left in circuit it would permanently 'degrade' the hearing, a switch actuated only when the 'watch' receiver is pressed against the ear is introduced in the circuit. Incidentally, this receiver enables the user to know when he is using sufficient pressure. It is not sufficiently recognized that in everyday use, pressing the telephone too lightly against the ear distorts sounds communicated. In the new table pattern 'neophone' telephone, the extra watch receiver is hung up by a hook. When lifted off and pressed against the user's ear, it is immediately available.

Hebrew University of Jerusalem

THE Hebrew University of Jerusalem, now entering its thirteenth year, is making a special appeal to the Anglo-Jewish community for increased financial support. A pamphlet issued by its "Friends" (199 Piccadilly, London) gives some account of the University's growth and present status. In grounds covering sixty acres on Mount Scopus, its buildings already include institutes of chemistry, physics, mathematics and meteorology, a library containing more than 300,000 books and an open-air theatre. A hospital and graduates' medical school and nurses' home are under construction, and plans have been prepared for a building for Jewish studies and the humanities. A department of radiology and experimental pathology, at present housed in the Straus Health Centre in Jerusalem, is engaged in cancer research, financed by a special endowment of £40,000. In a letter, reproduced in the pamphlet, signed by Lord Rutherford, Prof. Albert Einstein, Sir F. Gowland Hopkins, Sir William Bragg and others, it is pointed out that the University is the only one throughout the Near and Middle East in which scientific and scholarly research is a principal activity, and that some of the widely recognized work of its scientific institutes has been of immediate value to the whole population of Palestine. The director of its department of parasitology, engaged in the study of Mediterranean diseases, was chosen by the Royal Society to carry out investigations. Its department of hygiene and bacteriology maintains a malaria research station and has received subventions for its work from the Health Organisation of the League of Nations and the Government of Palestine. Jews in the United States contribute nearly half towards the annual budget of £80,000. Apart from endowments for two chairs and several scholarships, the Jewish community in England has hitherto borne an insignificant part.

Universities of Poland

POLAND'S universities are described in a bulletin recently published by the United States Government Printing Office, Washington (pp. 160. 25 cents). It is one of a series of studies undertaken at the request of the American Association of Collegiate Registrars by the Comparative Education Branch of the United States Office of Education. The institutions of higher education in existence in November 1918 within the boundaries of the new State then constituted reflected the influences, German, Austrian and Russian, of the Governments in whose territory they had been located, but have since been brought, along with a larger number of new institutions, into an organized scheme of training on university levels, all under the strict control of the Ministry of Public Instruction. The total number of regular students is 56,000, being one to 589 of the total population, a high proportion in comparison with those obtaining in other countries. The pressure for admission to many of the institutions such as the polytechnics, academy of mines and the medical schools of the universities, is so great that selection is made by competitive examination from

among the qualified candidates. In the small Free Polish University of Warsaw has lately been instituted an ingenious scheme under the name "Universitas Rediviva" for equipping aspirants to a liberal culture with a knowledge of things in general. The name refers to the medieval ideal of a university.

Science in Australia and New Zealand

THE Australian and New Zealand Association for the Advancement of Science is taking steps to give effect to the resolutions passed at the Auckland Meeting last January amending the constitution and by-laws relating to membership. Hitherto, ordinary members have paid a subscription of one guinea for each biennial session of Association; but it has been decided now to institute annual membership (one guinea per annum) and an elected fellowship (two guineas per annum). The fellows resident in Australia will constitute a committee to be known as the Australian National Research Council, which will have at its disposal for research and other purposes a sum not exceeding one half of the subscriptions of fellows and annual members resident in the Commonwealth. The Council will take over all the assets and responsibilities of the existing body of the same name which was brought into being early in the post-War period as the Australian member of the International Research Council. It is anticipated that one of its activities will be the institution of a periodical for the encouragement and dissemination of scientific knowledge among members of the general public.

The Brisbane Seismological Station

AN important and very welcome addition has recently been made to the chain of Australian seismological stations at Sydney, Melbourne, Adelaide and Perth. As an aid to the study of earthquakes in the south-west Pacific region, a station farther to the north was greatly needed. Interest in the foundation of one in Queensland was aroused by the occurrence of a tremor at Gayndah in April 1935, and a former student in the University of Brisbane offered to provide a Milne-Shaw seismograph. Later, the Council for Scientific and Industrial Research added a second instrument, so that both north-south and east-west components can now be recorded. According to an account given in the *Courier-Mail* (Brisbane) of June 2, the instruments are installed in the basement of the University's new library block. They were placed temporarily on their foundations about midday on May 31, and at 3.30 the next morning recorded an earthquake with its origin about 1,450 miles from Brisbane. The new station has been placed under the direction of Dr. W. H. Bryan, lecturer in geology in the University.

The American Chemical Society

THE ninety-fourth meeting of the American Chemical Society will be held in Rochester, New York, on September 6-10, under the chairmanship of Mr. M. H. Eisenhart, president of the Bausch and Lomb Optical Co. Seventeen professional divisions of the Society and the Microchemical Section will

hold sessions. Dr. E. R. Weidlein, director of the Mellon Institute of Industrial Research, Pittsburgh, will deliver the annual presidential address of the Society on September 7. At the twenty-three symposia, the following subjects will be discussed: developments affecting industry, nutrition, public health, pure science, and education; artificial radioactivity and its chemical uses, studies of the chemistry of the earth's crust, low temperature methods and research, chemical microscopy, quantitative spectroscopic analysis, and photography; chemistry and physics of electrical insulation; medicinal patents, vitamins, and the chemistry and metabolism of fats; cellulose derivatives; organic plastics; 'unit processes' and 'automatic control'; characteristic properties and chemical utilization of hydrocarbons; 'gaseous combustion'; investigations dealing with sugar, rubber, water, sewage, and sanitation, micro-chemistry, organic chemistry, fertilizers, and colloids.

The Selborne By-Pass

THE Selborne Society, which for fifty-two years has cherished the memory of Gilbert White, invites admirers of his life and work to make a copy of the following protest and send it signed to the Secretary of the Selborne Society, The Hermitage, Hanwell, London, W.7, so that it may be forwarded to the proper authority with the Society's own: "Understanding that powers are to be sought to drive a road, in the future, through the grounds of The Wakes at Selborne between the house and the Hanger which Gilbert White loved so well, I wish to protest against what would be an offence to the memory of a very great Englishman who made his village famous throughout the world and to urge that an alternative scheme, if necessary, be adopted.

Indian Institute of Science, Bangalore.

It is reported in *The Statesman* (India) of July 21, that, at a meeting of the Governing Council of the Indian Institute of Science, Bangalore, held on the previous day, Sir C. V. Raman accepted the appointment of professor of physics at the Institute at a monthly salary of 2,500 rupees (£187). The Council has appointed an interim director on a monthly salary of 1,000 rupees for one year, in addition to a registrar on 1,250 rupees. Rao Bahadur B. Venkatesachar, a member of the Council, has taken over charge of the directorship from Sir C. V. Raman and the latter has thus been relieved of all administrative duties, including the secretaryship of the Governing Council. The registrar is Mr. C. E. W. Jones, formerly director of public instruction, Central Provinces, who took up his new duties on July 31. (See also *NATURE* of June 26, p. 1102.)

'Vaseline' Products

THE manager of the Cheesbrough Manufacturing Co., Victoria Road, Willemsden, London, N.W.10, writes to point out that the word 'vaseline' is wrongly used in a letter by Mr. L. Bellingham in *NATURE* of July 10, and in the summary of the letter. The word is not a common designation, but

"is the trade mark or brand name used to distinguish the particular products marketed by this Company". The manager asks that the word 'vaseline' should not be used "unless in conjunction with and as the brand name applied to one of our products, such as 'Vaseline' Petroleum Jelly".

A History of Chemistry

AN interesting handbook issued by the Science Museum, London, S.W.7, entitled "Chemistry, a Brief Outline of its History and Development", by A. Barclay, gives an account of the history of chemistry, and is well illustrated, in some cases with representations of historical apparatus in the Museum. Apparatus used by Davy, Faraday, Graham, etc., is included. There are a good index and a bibliography. The subject is dealt with from the earliest period to modern times, the last section being on atomic structure. The handbook forms a useful and interesting supplement to text-books on chemistry. The price is 1s. 6d., post paid 1s. 8d., from the Museum or the sales offices of H.M. Stationery Office.

Announcements

THE Baly Medal for 1937 of the Royal College of Physicians has been awarded to Prof. E. L. Kennaway, professor of experimental pathology in the University of London and director of the Research Institute of the Cancer Hospital (Free), London. The award is made in recognition of Prof. Kennaway's biochemical investigations, which have led to the identification of a group of substances provoking malignant growth of tissues and having significant relations in structure to certain hormones and vitamins.

THE Warren Research Fund Committee of the Royal Society has appointed G. S. Hartley, of University College, London, and J. T. Randall, of the General Electric Co., Ltd., to Warren research fellowships, each to be held for four years in the first instance. Mr. Hartley proposes to carry out research on oil drops, films and solutions, and Mr. Randall will undertake a research on the mechanism of fluorescence in pure and impure solids.

THE Ministry of Health has approved the application of the Birmingham Corporation for sanction to a loan of £8,505 for the provision of a forensic science laboratory for the detection of crime.

THE publishers of *NATURE* have in stock a certain number of bound volumes for which space can no longer be found. The volumes extend from vol. 1 to vol. 91, with the exception of the following: vols. 3, 8, 15, 17, 19, 22, 23, 24, 25, 51, 53, 74, 76, 77, 79, 80, 83, 84, 85, 86. Librarians and others wishing to complete their sets of *NATURE* can be supplied with any of the volumes in stock, so long as the stock lasts, at the price of 2s. 6d. per volume, carriage paid. Application, with remittance, should be addressed to *NATURE* Office, St. Martin's Street, London, W.C.2. Volumes which are not applied for by the end of this year will be destroyed.

Letters to the Editor

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 242.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Differences in the Chromogenic Properties of Fresh-water and Marine Fish Liver Oils

WHEN vitamin A concentrates from marine fish livers are treated with antimony trichloride the blue solution normally exhibits an absorption maximum near 620 m μ with a subsidiary masked maximum near 693 m μ (displaced to 606 m μ and 572 m μ

We have also found, in addition, that the ultra-violet absorption spectra of the liver oils of fresh-water fish are differentiated from those of marine fish, in that the maximum is displaced from 328 m μ to 345-350 m μ (with, frequently, the appearance of another band at 280-285 m μ). The 340-350 m μ maximum thus appears to be associated with the 693 m μ antimony chloride chromogen, just as the 328 m μ band is associated with the 620 m μ chromogen.

Although most fresh-water fish liver oils show only one band near 693 m μ in chloroformic antimony trichloride, the absorption near 620 m μ is always appreciable. Thus the 693:620 intensity ratio seems to average 2:1, whereas for marine fish it is usually less than 0.2:1 (cf. Table 1 for the spectroscopic data on a few typical oils and concentrates).

The chromogenic properties of the two classes of liver oils reported here are closely parallel with those recently observed by Wald* when examining the retinas of

marine and freshwater fish respectively. It appears possible to us that the 693 m μ chromogen may be a second vitamin A with some degree of specificity for freshwater fish, and in this connexion an alcohol with six conjugated ethenoid linkages is obviously suggested as a possibility by the spectrographic data. We are at present engaged in an attempt to isolate the compound, and we also have the biological aspect of the question under test. It should, however, be noted that, until both biological and spectrographic data have been accumulated and examined, the accurate determination of the vitamin A content of liver oils of freshwater fish, by physico-chemical methods, is not possible.

respectively in oils of low potency). In exceptional cases, however, additional maxima at 635, 645, 656, 680 and 690-695 m μ have been recorded¹. The '693 chromogen' appears to be the most important of these extra chromogenic substances and follows the vitamin A during concentration into the richest fractions. When this chromogen has been recorded previously, in halibut oils, the intensity has usually been about one tenth of that due to the 620 chromogen². Recently, however, liver oils from certain Russian freshwater fish have been reported that gave antimony trichloride solutions exhibiting clear maxima at 645 or 690 m μ and only a weak band near 620 m μ ³.

We have since examined liver oils and concentrates from various freshwater fish by quantitative spectrophotometric methods and have consistently found them to be abnormal in exhibiting an absorption band in antimony trichloride solution at 690-697 m μ , or less commonly at 645 m μ , having an intensity greater than that of the 620 band. Up to twenty catches of each of the species quoted in the table were examined, the fish being obtained from the Volga or Don, or rivers in the Leningrad region.

TABLE 1.

Species	Liver oil or concentrate	Ultra-violet absorption		Antimony chloride blue test		Ratio of intensities 693/620
		Maxima† m μ	E 1% 1 cm.	Maxima† m μ	E 1% 1 cm.	
Catfish (<i>Silurus glanis</i>)	O	343 (281)	203 102	606 (620)	560 292	1.92
Pike (<i>Esox Lucius</i>)	O	345 (280)	187 124	606 (620)	445 240	1.85
Pike-perch (<i>Luciopeca Luciopeca</i>)	Oil	348 (283)	4.0 3.0	603 (606)	8.1 3.45	2.35

A Possible Vitamin A₂

THE antimony trichloride colour test for vitamin A is associated with a maximum absorption at 620 mμ. We have, since 1929, repeatedly encountered an additional band near 693 mμ, but further characterization of the chromogen has been hindered by the presence of excessive amounts of vitamin A. Thus, in halibut liver oils the relative intensities 620 mμ/693 mμ are c. 6:1, and in halibut visceral oils 10:1. The 693 mμ chromogen is rarely detectable in cod liver oils and never in our experience in whale liver oils.

It is frequently absent from the vitamin A fraction of eyes, but one of us (J.R.E.) has observed the 693 mμ band in extracts from goldfish eyes, the ratio 620 mμ/693 mμ being c. 1:1.5. Experiments on brown trout have shown that the 693 mμ chromogen occurs in the non-saponifiable extracts from livers and viscera. The 620 mμ band, as such, could not be detected. Direct absorption spectra showed the presence of three broad bands with maxima at 470, 350 and 287 mμ, respectively, the ultra-violet bands varying in intensity with the 693 mμ band in the colour test. Lederer and Rosanova¹ have also found an intense band at 693 mμ in the colour test applied to freshwater fish liver oils from the neighbourhood of the Murmanak Sea. We understand (private communication) that an apparent connexion between absorption bands at c. 345 and 285 mμ and the 693 mμ chromogen has been confirmed by Prof. Heilbron and Dr. Gillam on Lederer's oils. Wald's discovery that a substance apparently identical with the 693 mμ chromogen can replace the vitamin A of rhodospin *without loss of physiological function* runs parallel with the similar replacement in the viscera and liver of brown trout. It therefore seems desirable provisionally to designate as 'vitamin A₂' the 693 mμ chromogen with its characteristic ultra-violet absorption.

In chemical separations with liver oils, the 693 mμ chromogen follows vitamin A, the ratio 620 mμ/693 mμ for a given species remaining very nearly constant. It is not difficult with some liver oil extracts to reach $E_{1\text{cm}}^{1\%}$ 693 mμ 500–1,000, but judging from the amount of vitamin A present, the pure substance will have $E_{1\text{cm}}^{1\%}$ 693 mμ < 5,000. On this basis, each brown trout contains of the order 0.12 mgm. of the new material.

It seems clear that the 693 mμ chromogen is not in any simple sense an artefact derived from vitamin A; but the position remains obscure with regard to bands at 640 mμ and 660 mμ which occasionally appear in the colour test.

Specificity of Indophenol in the Estimation of Ascorbic Acid in Fermented Products

DURING the course of an investigation on the antiscorbutic value of Kaffir beer, it was observed that beers treated with a 2 per cent concentration of metaphosphoric acid gave high values for 'vitamin C' when titrated with indophenol in the usual manner, the values varying between 1.1 and 38.5 mgm./100 ml.

Delf¹, working with guinea pigs and monkeys, concluded that Kaffir beer was of slight antiscorbutic value. Levy and Fox², using hydrochloric acid for

acidification, examined eleven specimens of mine brewed beer and found values of 0.2–0.5 mgm./100 ml.

Bernbauer *et al.*³ showed that when *Aspergillus niger* was allowed to grow in sugar mixtures, substances with the same reducing properties as ascorbic acid were formed. Whether these possessed antiscorbutic activity or not was not clear (Kříženecký and Nevalonnyj⁴ and Hermann and Fodor⁵).

As with ascorbic acid, norite charcoal (Fox and Levy⁶) completely removed the reducing power. However, only a small fraction (0.8 mgm. out of 13.0 mgm.) was restored after hydrogen sulphide treatment. Hubbard squash extract (Tauber *et al.*⁷) entirely removed the reducing power. The folin uric acid reagent (Medes⁸) gave identical values with indophenol titration in the presence of 2 per cent metaphosphoric acid.

The effect of pH on the indophenol titration of the beer was as follows:

INDOPHENOL REDUCING POWER OF KAFFIR BEER AT DIFFERENT pH VALUES (in mgm. 'ascorbic acid' per 100 ml. beer).	
2.5 N HCl	8.0
1.2 pH	0.8
1.4	0.8
1.6	0.8
1.8	0.8
2.0	(doubtful end-point) 1.5
2.2	13.0
2.4	13.0
2.6	13.0

Guinea pig experiments showed the reducing substance to be almost devoid of antiscorbutic activity, the animals dying of scurvy in three to four weeks. Controls on orange juice remained healthy, and on autopsy showed no signs of scurvy.

The reducing power of the beer was followed at different stages of its preparation, and it was found that a large increase took place during the boiling of the mash, and a further increase during fermentation.

From these experiments it is concluded that the bulk of the reducing substance is not ascorbic acid. The true ascorbic acid content of the beer probably corresponds to the values of about 0.8 mgm./100 ml. obtained with the norite procedure and by titration at a pH between 1.2 and 1.8. The concentration was far too low to have any appreciable effect on the guinea pigs in the doses given. It is also shown that ascorbic acid oxidase (cf. Zilva⁹) and Srinivasan¹⁰), and the folin uric acid reagent (cf. Fujita *et al.*¹¹) are not specific for ascorbic acid.

Absorption of the Soft Component of Cosmic Radiation

It is now generally accepted that the soft component of cosmic radiation consists of electrons which are absorbed mainly by emission of light quanta and consequent production of pairs (cascade showers). The absorption of these particles is usually measured by two or more counters separated by a plate of some absorbing material of variable thickness. This method measures the probability of a primary electron either self penetrating the plate or producing at least one secondary electron emerging from the bottom of the plate.

Since the probabilities for the relevant processes are proportional to Z^2 , it is often assumed that the absorption curves for the soft component should be independent of the material when plotted on a scale proportional to NZ^2 (N = number of atoms per c.c.). This assumption, however, rests on an erroneous interpretation of the theory for the following reason.

Fig. 1.

The production of secondaries by the cascade process only takes place if the energy is higher than the critical energy E_c , at which the energy loss by radiation is equal to the energy loss by ionization. E_c is larger for light materials than for heavy ones. $E_c = 10 \times 10^6$ e.v. for lead; 60×10^6 e.v. for aluminium; 150×10^6 e.v. for air. Thus, the lower electrons from light materials will be more energetic than those from heavy materials. Naturally, the probability for the production of fast secondaries is smaller than that for slow ones. If we plot, therefore, the absorption curves on a Z^2 -scale, we should expect the curves to fall off more rapidly for light elements than for heavy ones.

We have calculated, on the basis of the quantum theory¹, the probability for an electron penetrating a plate of certain thickness or producing at least one secondary with energy greater than E_c . The curves obtained depend on the primary energy spectrum of the electrons. We have assumed a $E/E_c + 1$ law and have put $\gamma = 1$ and 2. For E smaller than the critical energy E_c for air, we assume the energy spectrum to fall off rapidly, the exact shape of the energy spectrum being of no importance for the result. The shape of the absorption curves is mainly determined by primary electrons with comparatively small energies, for which the validity of the theory is proved by direct experiments² (that is, up to 3×10^6 e.v. for lead and 10^6 e.v. for aluminium). The high-energy part of the spectrum only affects the tail end of the curves, which in any event cannot readily be distinguished from the hard component. (In Fig. 1 the curves are calculated assuming that the theory is valid for all energies.

Fig. 1 shows the theoretical absorption curves for lead (full) and aluminium (dotted) on an ordinary gm./cm.² scale. We see that to a rough approximation the curves follow an *ordinary mass absorption law*. The experimental points ($\circ$ for Pb, Δ for Al) are taken from the measurements by Auger, Ehrenfest and Leprince-Ringuet³. They are in good agreement with the theory for γ between 1 and 2. The accuracy is, however, not high enough to determine γ exactly.

Capture of Orbital Electrons

In two recent papers¹ Møller has shown that on the present theory of β -decay for a heavy nucleus emitting positrons of low maximum energy, the ratio F_K/F of the probability of K -electron capture to that of positron emission may be large. On the other hand, experiments by Jacobson² for a light nucleus (radio-scandium, $W_0 = 1.1 \pm 0.1$ MV., $Z = 21$) show that this ratio is $< 1/10$. We wish to point out that Jacobson's result is in agreement with a modified form of the theory³, but that this form makes a definite prediction about the low energy end of β -spectra.

The usual procedure of writing the interaction term as

$$(\psi_N^\dagger \Lambda' \psi_P) (\psi_e^\dagger \Lambda'' \psi_n) \quad \dots \quad (a)$$

where (N, P) (n, e) represent the heavy and light particles respectively, leads to a transition probability⁴

$$A \left| \int \psi_N^\dagger \psi_P d\tau \right|^2 (\psi_e^\dagger \psi_e) (W_0 \pm W)^\alpha \quad \begin{matrix} \alpha = 2 \text{ Fermi} \\ \alpha = 4 \text{ Konopinski-Uhlenbeck} \end{matrix}$$

The $\pm$ sign depends upon the electron being absorbed from a state of positive or negative energy. For the ratio F_K/F the evaluation of $(\psi_e^\dagger \psi_e)$ from the known form⁵ of the wave-functions for a K -electron, gives for small Z

$$F_K/F = 2\pi\gamma^2 (W_0 + 1)^\alpha \int_1^{W_0} W(W^2 - 1)^{1/2} (W_0 - W)^\alpha \quad \begin{matrix} \alpha = 2 \text{ Fermi} \\ \alpha = 4 \text{ Konopinski-Uhlenbeck} \end{matrix}$$

where $\gamma = Z/137$.

If $Z = 21.0$, $F_K \sim 0.22$ for $\alpha = 2$, and 2.3 for $\alpha = 4$. F depends sensitively upon the exact value of W_0 , varying from 0.63 to 1.17 in the Fermi case, and from 0.39 to 1.0 in the Konopinski-Uhlenbeck case, as W_0 varies from $2.2 mc^2$ to $2.4 mc^2$. We therefore require a very precise knowledge of W_0 to determine F_K/F exactly. Even with $W_0 = 2.4 mc^2$, F_K/F is about 1/5 for $\alpha = 2$, and 2.3 for $\alpha = 4$, so that the K -electron capture could scarcely have been overlooked, particularly in the Konopinski-Uhlenbeck case.

There is the further possibility of writing the interaction term in the form

$$(\psi_N^\dagger \Lambda' \psi_n) (\psi_e^\dagger \Lambda'' \psi_P) \quad \dots \quad (b)$$

(This corresponds to the case $C = -1$ in the note recently published by Mercier⁶. For this value of C , however, the formulæ there given are not applicable.)

For $Z \sim 20$ the components ψ_1, ψ_2 of the K -electron are small compared with the components ψ_3, ψ_4 . Similarly, ψ_p has two large and two small components differing by a factor of the order of 1/10. We may suppose Λ^* to be an operator combining the two small components of ψ_p with the two large components of ψ_3 . This arrangement gives a factor 1/100 in the terms containing the small proton components, and a factor 1/200 in the terms containing the small electron components. Thus, by addition, F_2/F will contain a factor 3/200 from this combination; that is, for $Z = 21.0$, we may take F_2 to be 0.003 for $\alpha = 2$, and 0.035 for $\alpha = 4$. The positron emission will now be given by

$$F = A \int_1^{\infty} W \cdot (W + 1) (W^2 - 1)^{1/2} (W_0 - W)^{\alpha} dW \quad (c) \quad \begin{matrix} \alpha=2 \text{ Fermi} \\ \alpha=4 \text{ Konopinski-Uhlenbeck} \end{matrix}$$

F will again depend sensitively upon the value of W_0 , but we can take as suitable values 1.5 for $\alpha = 2$ and 0.75 for $\alpha = 4$. This gives for F_2/F approximately the values 1/500, $\alpha = 2$, and 1/25, $\alpha = 4$. It is possible that K -electron capture for the ratio 1/25 has escaped detection, although its existence should be revealed by further experiments. The interesting point arises that, if the $\alpha = 4$ interaction is assumed, we obtain a definite prediction of the low-energy end of the positron spectrum, which is given by the integrand of (c). This leads us to expect a large number of slow positrons. It is important to note that this latter conclusion seems to hold only for allowed transitions. For forbidden transitions (c) has a more complicated form.

In the Fermi theory, F_2/F is about 1/3 or 1/500 according as one adopts the law (a) or (b). The actual interaction law may also be a linear combination of (a) and (b), and it is easy to calculate the proportion necessary to give any intermediate ratio. It should be noted that, as this ratio decreases from 1/3, we require a rapid increase in the percentage of (b); for example, when the ratio has decreased to 1/30 we already need more than 90 per cent of the interaction (b).

We see that if we accept the experimental evidence that the probability of absorption of a K -electron relative to that of positron emission is less than the value required by the Konopinski-Uhlenbeck theory, then the theory must be replaced by a modified form which gives many more slow positrons and fewer slow electrons. This appears to be in reasonable agreement with the direct observation of the spectrum.

the microphotometer curves of the resultant pattern reveal clearly four distinct components of $H\alpha$ with intensities and positions roughly as given by theory. There are no ghosts in the Lummer plates and the interference of lines of the secondary spectrum of hydrogen has been eliminated.

We are now engaged in obtaining quantitatively the intensity and position of these components.

We feel that this method (new, so far as we know) may be of service in the study of the fine and hyperfine structure of the spectrum lines of other elements.

Raman Spectra of Oxonium Compounds

M. WOLKENSTEIN and G. K. SYRKIN have published in a recent communication in *NATURE*¹ the Raman spectrum of equimolecular mixtures of ether and hydrogen chloride in the liquid state¹. In 1935 we studied² the Raman spectrum of the system ethyl ether plus hydrogen bromide at low temperature (228° K.) and announced there further work on this subject. The publication of these results was delayed owing to unforeseen circumstances.

We investigated solutions of the compound $\text{CH}_3\text{OH} + \text{HCl}$ (HBr), $\text{C}_2\text{H}_5\text{OH} + \text{HCl}$ (HBr) ($\text{CH}_3\text{O})_2 + \text{HCl}$ (HBr) and $(\text{CH}_3)_2\text{CO} + \text{HCl}$ (HBr) in excess of hydrogen halides. The compounds were prepared, dissolved in excess liquid hydrogen halide and the resulting solution filled into the Raman tube, all in one operation, in a high vacuum apparatus at low temperatures, thus eliminating all possibilities of chemical reaction (formation of R. Hal.). Under these conditions, we obtained spectra of the solutions which were characteristically different from the spectra of the components. We obtained the following frequencies:

$\text{CH}_3\text{OH} \dots \text{HCl}$ ($t = -75^\circ \text{C}$, molecular ratio = 1:1.8). 465(3), 645(3), 991(4), 1083(5), 1181(1), 1357(3), 1440(5), 2955(10), 3019(7), 3364(3).

$\text{CH}_3\text{OH} \dots \text{HBr}$ ($t = -63^\circ \text{C}$, mol. ratio = c. 1:5). 391(3), 497(4), 639(4), 887(2), 984(3), 1066(3), 1440(8a), 2907(4), 2970(10), 3047(5).

$\text{C}_2\text{H}_5\text{OH} \dots \text{HCl}$ ($t = -75^\circ \text{C}$, mol. ratio = 1:2.1). 398(3), 507(3), 613(3), 646(3), 873(3), 1021(3), 1094(2), 1281(2), 1343(3), 1450(6), 2923(8), 2977(10), 3357(1).

$\text{C}_2\text{H}_5\text{OH} \dots \text{HBr}$ ($t = -65^\circ \text{C}$, mol. ratio = c. 1:5). 431(2), 530(4), 597(4), 706(3), 829(5a), 925(1), 1048(3), 1290(1), 1377(2), 1450(6), 2940(8), 2984(10).

$(\text{CH}_3)_2\text{O} \dots \text{HCl}$ ($t = -80^\circ \text{C}$, mol. ratio = 1:2.5). 356(1), 433(3), 505(3), 800(7a), 947(1), 1006(1), 1063(3), 1444(8a), 2323(6), 2323(10), 3003(9).

$(\text{CH}_3)_2\text{O} \dots \text{HBr}$ ($t = -51^\circ \text{C}$, mol. ratio = 1:1.7). 265, 396(3), 506(3), 824(7b), 896(3), 965(1), 1023(1), 1440(8a), 2334(4a), 2348(10b), 3037(9a).

$(\text{O}_2\text{H})_2\text{O} \dots \text{HCl}$ ($t = -80^\circ \text{C}$, mol. ratio = 1:3.5). 337(1), 418(2), 491(3), 767(3), 823(3a), 955(3), 997(3), [1058(1)], 1370(3), 1450(7), 2373(1), 2942(10), 2981(10).

$(\text{O}_2\text{H})_2\text{O} \dots \text{HBr}$ ($t = -45^\circ \text{C}$, mol. ratio = 1:2.5). 303(1), 406(5), 470(1), 673(1a), 830(0), 920(0), 996(4b), 1071(1), 1137(0), 1263(1), 1459(6b), 2356(0), 2940(10), 2984(10).

The detailed discussion of the spectra led to the conclusion that the compounds do not exist in solution of excess hydrogen halide as 'oxonium' compounds $(\text{R}^+ \text{O} \text{H}) + \text{X}^-$, but as compounds with tetravalent oxygen. We propose calling this type a compound an 'oxan' compound.

Structure of $H\alpha$ of Hydrogen

THE structure of the lines of the Balmer spectrum of hydrogen was investigated in this laboratory some years ago. Recently we have attacked the problem again, using two Lummer plates, not crossed as in the investigations of Kent, Taylor and Pearson¹, but dispersing in the same plane. With this arrangement,

The question whether the former addition compounds appear as oxonium or oxan compounds is to a high degree dependent on the physico-chemical conditions (temperature, state of aggregation, solvent, etc.). By varying the conditions, a gradual transition from the 'oxonium' to the 'oxan' form is possible. It is not improbable that equilibria exist between the two above-mentioned extreme types. We have started a more intensive examination of this question.

A detailed account of the Raman investigations, as summarized above, will be published in the *Zeitschrift für physikalische Chemie* (B).

Visible Adsorbed Films and the Spreading of Liquid Drops at Interfaces

THE adsorption isothermals of benzene and methyl alcohol vapours at the surface of mica are of sigmoid form, concave to the pressure axis until the first monolayer is nearing completion, and thereafter becoming more and more steeply inclined to it as saturation is approached. Though the adsorption energy decreases on completion of the first monolayer to a value very near the normal heat of liquefaction, the polymolecular films formed at saturation have properties quite different from the bulk liquids. This is strikingly demonstrated in a series of experiments we have recently carried out, a few of which are briefly recorded in this note.

When a freshly split mica plate is placed under a jet of the supersaturated vapour of benzene, methyl alcohol or water, condensation of bulk liquid does not occur until a film of critical thickness has been built up. By suitably controlling the conditions, films of thickness less than this, yet thick enough to show interference colours, are readily produced. A drop of the same liquid, placed on such a film, may flatten, but does not lose its identity as a lens, showing that the angle of contact, though small, is finite. Methyl alcohol, which spreads rapidly on fresh mica in the open air, will not do so in the presence of its own supersaturated vapour; on the contrary, a spread film was found to break up into drops when brought under the vapour jet. The alternative view as to the origin of the film colours, namely, that they may be due to diffraction from a mist of invisible droplets, is not borne out by the facts; for example, we were able to float lenses of different liquids right across the films without disturbing them in any way.

Much evidence has been found by us in favour of Hardy's view¹ that a drop of pure liquid placed on a clean solid surface invariably reaches a stable state only when a single lens is in equilibrium with an adsorbed film. Without permitting ourselves this degree of generality, we would emphasize the marked sensitiveness of the contact angle to changes in the degree of saturation of the vapour phase, and to the presence therein of even traces of a second adsorbable component; both these effects are often neglected in making measurements of contact angles.

Interesting effects are produced by placing drops of different liquids near each other on a mica plate, and these are at least rendered less incomprehensible

by the realization that adsorbed films can be thick, and that the energy relations at the edge of a drop are markedly dependent on the local concentration of the second component of the film. If a drop of concentrated acetic acid, containing enough water to prevent its spreading, is placed near one of the very dilute acid (or of water) resting on clean mica, the former first elongates, then advances towards the dilute acid. Before contact, however, the latter drop is sharply repelled and driven forward to the edge of the plate. Arriving there, it is usually repelled by the edge, with the result that it dodges round its pursuer (which is attracted to the edge and remains clinging there), and comes to rest in the centre of the plate. A similar behaviour has been observed with other pairs of liquids, though the 'edge' effect is often less noticeable; for example, a lens of *n*-hexane will drive one of benzene in front of it until the former has all evaporated.

The highly convex lenses formed by hexane drops on mica spread immediately when brought under the jet of benzene vapour, whilst lenses of benzene condense on the spread film. The incomplete miscibility of hexane and benzene in the form of drops on mica is astonishing, though numerous other examples might be quoted. If a drop of hexane is placed on top of one of benzene as it rests on mica, the mixture divides itself into two parts—a spread film which quickly evaporates, showing interference colours, and a lens (mainly of benzene) which is repelled rapidly to the edge of this film. The possible application of such phenomena as a means of effecting separations immediately suggests itself. The drops used in these experiments must of course be small.

Reliability of Pacific Seismological Stations

IN a former paper I gave a comparison of the accuracies of seismological stations, based on the residuals for *P* in the International Seismological Summary¹. The fraction of the residuals between $\pm 4s$ was taken as the standard and called the 'reliability'. It came out rather low for most of the Pacific stations, though I suggested that the estimates might be too low, on account of errors in the epicentres due to too little weight having been given to the near stations. In some work on southern earthquakes, preparatory to a further study of the core waves, I have re-determined a large number of Pacific epicentres (up to the end of 1931), taking into account the effects of the ellipticity of the earth; the result is a great improvement in the reliabilities. They are now as follows:

Riverview, 17/17 = 1.0; Melbourne, 14/16 = 0.9; Apia, 8/10 = 0.8; Adelaide, 11/16 = 0.7 (probably too low as distant earthquakes give 11/12 = 0.9); Manila and Wellington, 13/17 = 0.8; Christchurch, 8/11 = 0.7; Amboina, 10/15 = 0.7; Batavia, 11/16 = 0.7; Honolulu, Perth and Malabar, 0.6; Sydney, 0.4; the rest, nearly as before.

Most of the change is due to the correction for the ellipticity of the earth, provided by Bullen². At

large distances this varies with azimuth by nearly 5 seconds when geographical co-ordinates are used, and introduces a large systematic error into southern epicentres if it is not allowed for. Bullen and I found on determining epicentres from the nearer stations¹, that southern earthquakes habitually showed negative residuals of about $-4s.$ at great distances, and attributed these to slight focal depth; it appears now, however, that they were entirely due to the ellipticity. The great majority of Pacific earthquakes can be taken as having foci at an inappreciable depth.

The law of error in seismological observations seems to be practically the normal law with a uniform distribution superposed. The standard error corresponding to the normal part is found to be $2.0s.$ both for the good and for the intermediate stations; the difference between them is not in the accuracy of the normal observations, but in the frequency of defective ones, usually attributable to microseisms and weak beginnings.

There appears to be a slight difference between Pacific and continental travel times, amounting to about $2s.$ for $P.$ between 5° and 50° out of a total time of 8 minutes, and indicating a higher velocity below the Pacific. This might be expected if there has been more cooling below the oceans than under the continents. Larger differences have been claimed previously, of the order of 10 per cent, but these are rendered impossible by the observations now available.

Magnetic Quality of Nickel Wire as Influenced by the Surface

IN a previous note¹, test data were given which showed the very large increase of magnetic permeability of nickel wire which could be obtained by applying to the surface a thin skin of copper and allowing it to soak for some hours at a sufficiently high temperature.

The influence of the surface of a wire on its magnetic quality has been examined further as follows:

Fig. 1.

Commercially pure nickel wires of diameters $1/32$ in., $1/16$ in., and $3/16$ in. respectively, were heated in an atmosphere of hydrogen for a sufficiently long

time to reach a condition of maximum permeability in each case. After having cooled slowly to room temperature, the magnetization curves for each wire was obtained and these curves are shown in Fig. 1.

It will be seen that the initial portion of the curve for the $1/32$ -in. diameter wire is very flat and this part of the curve becomes steeper as the diameter increases. That is to say, the greater the ratio of surface perimeter to cross-sectional area, the less easily is the wire magnetized for low values of H . In other words, the magnetic characteristic of the wire is intimately dependent upon the diameter. The tests have also shown that the remanence and the coercive force are both considerably greater for the wire of $1/32$ in. diameter than for the other wires.

These results have important theoretical and practical implications, which will be considered in a paper which is now in course of preparation for publication elsewhere.

Darkening of some Commercial Titanium Dioxide in Daylight

DURING an investigation of the discoloration by light of some ceramic glazes containing titanium compounds and of the subsequent fading of the discoloration when the glaze is kept in the dark¹, it was observed that certain varieties of commercial titanium dioxide are themselves affected by daylight. These varieties pass from their normal creamy colour to a deeper yellow-brown tint on exposure. The original colour is restored in the dark. This property of some commercial titania appears to have escaped notice in Great Britain, though Lee², in his study of reversible photo-sensitivity in haackmanite, draws an analogy with a certain brand of titania which showed the property mentioned in this letter.

The samples of titanium dioxide studied were stored in ordinary glass vessels exposed to daylight transmitted through the glass of the laboratory windows. The darkening of the titania, observed against samples kept in the dark, was apparent after only three hours in some instances. The effect is shown by those particles or perhaps portions of particle-surfaces adjacent to the illuminated glass wall of the container. Hence it is important that the powdered titania should move as little as possible during illumination if the darkening is to be obvious.

No experiments were made with the photo-sensitive brands of titania as components of paints or pigments, but they conferred similar properties on some ceramic glazes containing them. However, ceramic glazes darkening in light were made from titania and from rutile where these materials themselves showed no apparent darkening.

A definite explanation of the darkening of titania cannot be cited, though it appears likely that the colours shown by the exposed and by the unexposed material mark the establishment of an equilibrium condition of either a chemical or a physical nature. A chemical explanation might involve the oxidation of ferrous iron present in the titania to a more deeply coloured ferric compound (cf. the possible

mechanism for the darkening effect of titania on the colour produced by iron in enamels³). Titania is a source of photo-activation of chemical processes, including some oxidation processes⁴. Less likely is a change in the state of oxidation of the titania itself. (Renz discusses the reduction of titania in light in the presence of certain organic liquids and reducing solutions⁵.) Among physical explanations, changes in the crystalline variety of titania present (of the crystalline phases known to mineralogists as rutile, anatase and brookite) or in the grain-size of the titania do not seem very probable. Alteration in the degree of dispersion of some colloidal material suspended in the titania is another possibility (see, for example, the summary of Doelter's work given by Lee⁶ and the references provided by Clarke⁶).

The above suggestions are by no means exhaustive, and the possibility of a connexion between the darkening of some titanium dioxide by light and the darkening of titania on heating should be borne in mind. Meanwhile, notice of the phenomena described may be of value to those workers interested in titanium and its compounds.

I wish to thank Dr. Harry W. Webb for reading through this letter.

A New Form of Resorcinol

A NEW form of resorcinol has recently been investigated in this Laboratory which compares as follows with the structure already described by Robertson¹.

	α -Resorcinol	β -Resorcinol (new form)
space group	C_{2v}^2 (Pna)	C_{2v}^2 (Pna)
axes		
a	10.53	7.91
b	9.53	12.57
c	5.66	5.50
cell volume	568 A. ³	547 A. ³
molecules per cell	4	4
molecular symmetry	none	none
calculated density	1.278	1.327

The principal intensities and higher orders of single crystal X-ray photographs show that the molecules in the β -crystals have turned round to align themselves in the b -axis direction.

The new form is conveniently prepared by slow evaporation of benzene solutions at ordinary temperatures, using specially dried air². Vacuum sublimation of resorcinol under certain conditions gives a preponderance of β -crystals, in large shiny flakes, which can easily be distinguished from the long needles of the α -form. According to Lantz³, resorcinol undergoes a transformation above 70.8° C. into a denser modification, which is perhaps identical with the β -form.

The two forms of resorcinol are of considerable interest for the theory of intermolecular resonance, since the hydroxyl 'bonds' in the two structures need not necessarily be of the same length. Although

this point can only be decided by a quantitative measurement of intensities of reflection, the manner of discovery of the β -form suggests that a difference in the hydroxyl bonds is quite possible. Repeated crystallization of resorcinol from 99.6 per cent 'heavy' water gives a deuterio-resorcinol which, according to Munzberg⁴, has the structure $C_6H_4D_2(OD)_2$. Whereas $C_6H_4(OH)_2$, when crystallized from boiling benzene gives good crystals of the α -form, the deuterium compound gives poor feathery crystals of the β -form; in one case a crystal was obtained which had the α -structure at one end and the β -structure at the other. On vacuum sublimation, $C_6H_4D_2(OD)_2$ again behaves differently in giving a preponderance of crystals with the α -structure.

The thermodynamic relationship between the two forms and their magnetic anisotropy are being measured. The possibility of a transformation from one form to the other in the solid should perhaps be considered in connexion with temperature effects described by Nilakantan⁵.

Carbon-Halogen Distance in the Methyl Halides

In attempting to correlate the data on inter-atomic distances in polyatomic molecules, certain serious discrepancies have come to light between the spectroscopic method and the diffraction method as regards the carbon-halogen distances in the methyl halides. The differences are tabulated in Table 1. The reason that this had not been noticed earlier is that certain mistakes have been present in the deductions from the spectroscopic data and also that many new data are available. These results are particularly interesting when compared with the corresponding distances in the carbon tetrahalides,

TABLE 1.

	Old spectroscopic value ¹	New spectroscopic value	Diffraction value ²	Value in CX_4 ³
CH_3F	1.4	1.385 ± 0.004	1.42 ± 0.02	1.36 ± 0.02
CH_3Cl	1.8	1.65 ± 0.05	1.77 ± 0.02	1.765 ± 0.005
CH_3Br	2.0	1.88 ± 0.06	2.06 ± 0.06	1.93 ± 0.03
CH_3I	2.05	2.12 ± 0.15	2.13 ± 0.06	—

which are given in the last column. Thus it will be seen that, according to the diffraction method, in the methyl halides the carbon-halogen distance is always greater than, or equal to, the corresponding distance in the tetrahalides, whereas the spectroscopic method would seem to indicate that exactly the opposite is the case. The latter seems much more likely from consideration of the mutual repulsion of the halogen atoms in the tetrahalides.

Further support for this interpretation comes from an examination of the force constants for the C-halogen bond in the two cases. These are compared in Table 2, where it will be noticed that the force constant is always considerably larger in the methyl

halide than in the tetrahalide. The force constants in the first column were obtained by the method of Sutherland and Dennison¹, while those in the second were obtained by that of Urey and Bradley².

TABLE 2
Carbon-halogen force constants in 10⁶ dynes/cm.

	C—F	C—Cl	C—Br
CH ₃ X	5.8	3.6	2.9
CH ₂ X	4.0	1.8	1.4

One may not convert this difference in force constant into a difference in internuclear distance directly by means of the Clark³ or the Badger⁴ relation, since the bonds are under considerable strain in the tetrahalides. Badger, however, has shown how it is possible to make an allowance for this and has actually predicted a difference of 0.19 Å. between the C—Cl distance in CH₃Cl and CCl₄. This is of the same order as that found above.

Duchesne⁵, and Linnett and Thompson⁶ have recently remarked on the apparent large change in the C—C force constant in going from C₂H₄ to C₂Cl₄, and have suggested interpretations involving resonance between different structures. It seems probable, however, that at least a part of this change is due to the C—C bond being under a strain in C₂Cl₄ from the mutual repulsions of the Cl atoms. The potential functions used by Duchesne took no account of interaction between the Cl atoms.

A full treatment of these matters will be published in due course.

Oestrogenic Substances in the Dead Sea

THE Dead Sea, situated at one of the deepest points of the earth, contains a high concentration of salts (more than 25 per cent). In the depth of the Dead Sea there is a sandy mud which we have found to exhibit a certain oestrogenic activity. For the mud of the southern part of the Dead Sea the oestrogenic activity is about three times as great as for the northern part. The deep sea water contains 100 M.U. per litre, while the surface water is free of oestrogenic substances. The salt manufactured from the Dead Sea (salsana) contains 100 M.U. per kgm. Our results are given in the following table.

Part of the Dead Sea	Depth	Hormone activity (M.U. per litre)
<i>A. Water.</i>		
North near Kallia	Surface	Less than 6.6
" " "	Near the bottom	100
South	Surface	Less than 20
<i>B. Mud</i>	M.U. per kgm.	M.U. per kgm. dry weight
North near Kallia	30	45
South	100	100
<i>C. Salsana</i>		100

Other steroid hormones (male sex hormone, progesterone) could not be detected.

The mud was found to contain a yellow dye-stuff which according to its physical properties (absorptor and fluorescence spectra *inter al.*) belongs to the lyochrome group.

Maturation in the Thelytokously Parthenogenetic Tenthredinidae

SINCE Doncaster's preliminary work in 1908¹, nothing has been recorded on the maturation of the thelytokously parthenogenetic Tenthredinidae. This author concluded that the chromosome number in the oocyte, polar nuclei and egg pronucleus was 8, and that there were two maturation divisions giving rise to an egg pronucleus and three polar nuclei². Recent work on the species *Pristiphora pallipes* Lep., by our colleague, Mr. L. O. Comrie, raises strong doubts regarding Doncaster's interpretations on chromosome number and behaviour, but confirms him regarding the number of maturation divisions and polar nuclei.

In the thelytokously parthenogenetic species *Thrinax macula* Kl., we find that in the female-producing egg there occurs only one maturation division, non-reductional, with the formation of one polar nucleus. Evidently there exist different methods of maturation in the thelytokously parthenogenetic saw-flies.

Doncaster's species are thelytokous, with rare males, whilst *Thrinax macula* reproduces by obligatory parthenogenesis (in the laboratory at least), though certain females parthenogenetically produce all-male (or almost all-male) broods, such males being found reproductively useless.

The female chromosome constitution is $2n = 14$, that of the male possibly $n = 7$. Good oögonial figures, not easily obtained, show 12-16. Chromosomes of the maturation spindle at no time exhibit tetrad formation; each of the 14 chromosomes is split longitudinally; 14 travel to each pole, arranged, very often, temporarily as 7 couples. Two vesicles are formed, the inner sinking into the yolk without further maturation.

The polocyte is either extruded or it divides on a wide asterless spindle and displays clearly 14 large rod-shaped chromosomes split longitudinally. The outer group derived from this division is extruded from the egg, but the inner group becomes vesicular, may undergo a further division, and ultimately degenerate.

Embryonic tissues show approximately 12-14 very small chromosomes. Follicle cells from pupal ovaries best show the number (14), morphology and arrangement of the chromosomes. Corroborative counts from other tissues are obtainable during metamorphosis, though polyploid spindles are more common, especially in tracheal and gut cells.

Spermatogonia have not been obtained. The first spermatocyte division is abortive and a minute cytoplasmic polar bud is nipped off. The second spermatocyte with 7 chromosomes produces two spermatids each with 7 chromosomes. In several cases were seen whole cysts of cells with 7 loosely arranged pairs of chromosomes; we interpret them

provisionally as 7 split chromosomes of the first spermatocytes preparing for the second (equational) division. The cytology of male maturation and spermatogenesis therefore closely resembles that typical of *Hymanoptera*.

Attention is directed to these considerations regarding *T. macula*: (1) In our experience the chromosome number of 14 is very exceptional among saw-flies, for some 40 species studied by ourselves and our colleague, Dr. F. Greenshields, show that 16 is usual (possibly it is 12 in a species of *Claudius*). (2) Its autoregulation behaviour is 'orthodox', for such occurs in the majority of animals thelytokously parthenogenetic. (3) It is uncertain whether the female chromosome constitution (14) is double that of the male, though the count of 7 in the male spermatocyte supports this view.

Our conclusions have been reached from intensive study of abundant material. The usual fixatives were used, but Petrunkewitch gave the best result with eggs; for the most part we stained with iron hæmatoxylin, but gentian violet, safranin and Fuenlen's reagent gave good results.

This work has been done with the assistance of a grant from the Department of Scientific and Industrial Research and whilst one of us (A.R.S.) is a teaching fellow under the Carnegie Trust. To both these bodies we give our thanks.

Body Orientation in Crustacea

THERE is, I think, a fallacy which is frequently made in many of the problems dealing with the body orientation of Crustacea. I believe that practically all biologists dealing with this subject have accepted the idea that the position of the centre of gravity is a matter of great importance. Thus, to quote just one of the many statements which have been made along these lines: S. R. Williams¹ says, "A sinking animal, like a lifeless body, always falls with the heavy end downwards." Lifeless bodies do not sink with the heavy end downwards unless their specific gravity is considerably greater than the liquid in which they are sinking. Not only can this be demonstrated by experiment but also it is in agreement with standard text-book hydrodynamics.

Fig. 1.

A CONE OF THIS SIZE AND SHAPE MADE OF ASH, SPEC. GRAVITY 0.817, SINKS HORIZONTALLY IN PETROL, SPEC. GRAVITY 0.74 AND RISES HORIZONTALLY IN A MIXTURE OF ALCOHOL AND WATER, SPEC. GRAVITY 0.95.

Recently I have made a series of cones of different materials (Fig. 1). In all cases the diameter at the

base was a quarter of the length, but, in addition, the broad end of the cone was made hemispherical. The centre of gravity of the cone itself would, of course, be three quarters of the distance from the tip, while the hemispherical attachment would bring the centre of gravity still farther from the point. The cones were made of different kinds of wood, box, mahogany, ash and ebony while the liquids used were water, water and alcohol, petrol. Ash floats in water but sinks in petrol. Box just floats in tap-water but will sink after it has been soaked for several days. Another excellent material is the ordinary carrot, which will always sink slowly in tap-water. The size of the cones varied from half an inch in length to six inches. It is unnecessary for me to give the actual figures for the specific gravities here; suffice it to say that a cone of the shape figured either sinks or rises horizontally, although the position of the centre of gravity is very definitely towards the one end.

To get satisfactory results, the specific gravity of cone and liquid must be reasonably close, and it is much easier to obtain the horizontal position with small cones. Cones were made of zinc, tin, lead and iron, and any of these drop through tap-water with the heavy end first.

From the above experiments, it is, I think, definitely proved that provided the lifeless body sinking or rising is doing so in a liquid that approximates its own specific gravity, the position of the centre of gravity has very little influence. There is very little definite information about the actual specific gravity of living Entomostraca. Several attempts have been made to find it, but since these have all been made either with a dead or narcotized animal which was made to float in liquids of known specific gravity, the result can only be a rough approximation.

However, it is quite certain that in most cases the animals are just slightly heavier than the liquid in which they are swimming. According to Williams, the specific gravity of *Cyclops albidus* is 1.022 while that of *Cypridopsis vidua* Muller (an oetradod) is 1.046; since the specific gravity of any natural water must be above 1.0, it is fairly clear that an additional spine or a slight increase in the extension of the head of a *Daphnia* cannot affect body orientation by influencing the position of the centre of gravity.

This is scarcely the place to discuss the somewhat voluminous literature on the subject, but the position of the centre of gravity plays a very large part in Woltereck's theory², which has been discussed somewhat fully by Skogsberg³ and accepted. It has also been accepted by Wagler⁴. From the mathematical point of view (I am greatly indebted to one of my colleagues, Mr. H. C. Nest, for looking up this theorem for me) the matter is treated fully by Ramsey in "A Treatise on Hydromechanics", Part 2: "Hydrodynamics", p. 190, "Stability". At the end of the theorem it is stated that "this accords with the observed tendency of a body to turn its flat side or its length across the direction of its motion".

To put the matter more crudely: when a body is sinking through a liquid, the most stable position is one in which it presents the greatest area in the horizontal plane. In other words, there is a very definite tendency which brings the greatest possible plane into the horizontal position; but if the speed of sinking is at all great, other factors may influence the attitude taken up by the sinking bodies. Small Entomostraca, even though the specific gravity of

chitin may be as high as 1.4, are incapable of sinking rapidly. Actually the chitinous casts of Daphnids sink quite slowly; so do those of freshwater ostracods.

The swimming, floating and sinking of these minute crustaceans at present constitutes an almost impossible problem, and it depends, I believe, entirely on the nature of the eddies and vortices set up. Mere speculations, though they may be very attractive, are not likely to carry one very far; but I think one can safely conclude that with organisms comparable in size and specific gravity to *Daphnia* or *Chirocephalus* the position of the centre of gravity

plays no part whatsoever as a factor determining body orientation.

Points from Foregoing Letters

Prof. I. M. Hailbron, A. E. Gillam and Drs. E. Lederer and V. Rosanova have spectrographically examined the liver oils and vitamin A concentrates from more than sixty batches of seven different species of freshwater fish, and find that the main absorption bands are at 693 m μ (and inflection 620 m μ) for chloroformic antimony trichloride, and 345 m μ for alcohol. These properties are in contrast to those of marine fish and mammalian liver oils and concentrates, where the corresponding maxima are 620 and 328 m μ respectively, and may possibly be due to a second vitamin A with some degree of specificity for freshwater fish.

A substance with absorption bands at 350 and 287 m μ , giving a green colour with antimony trichloride (λ_{max} 693 m μ), is stated by Drs. J. R. Edisbury and R. A. Morton, and G. W. Simpkins to appear in the liver, viscera and sometimes eyes of fish, particularly freshwater fish. It resembles vitamin A so closely that it is tentatively designated 'vitamin A₁'.

F. W. Fox and W. Stone state that a substance other than ascorbic acid and having no antiscorbutic activity is formed in large quantities in Kaffir beer. It behaves as ascorbic acid with indophenol at a pH higher than 2.0, with the folin uric acid reagent, and with ascorbic acid oxidase. It does not react as ascorbic acid with norite charcoal or with indophenol at a pH between 1.2 and 1.8.

Theoretical curves for the absorption of the soft component of cosmic radiation by lead and aluminium have been calculated by Dr. W. Heitler on the basis of the quantum theory. The few available values from experimental measurements fall satisfactorily on these curves.

F. Hoyle states that, to account for the result of Jacobson's recent experiments, it is necessary to assume a β -decay interaction term which combines the wave-functions of the heavy and light particles in a more interrelated form than the expressions proposed by Fermi and Konopinski-Uhlenbeck. This modification makes more definite predictions of the low-energy end of positron and electron spectra, which seem to give reasonable agreement with the empirical β -decay curves.

From the Raman spectra of solutions of ethyl ether in excess halogen acids, Dr. G. Briegleb and W. Leuppe conclude that, in solution, they form 'oxan' compounds containing tetravalent oxygen.

By directing jets of supersaturated vapours of common liquids against surfaces of mica, Prof. D. H. Bangham, S. Mosallam and Z. Saweris have produced films which give rise to interference colours, and yet

have properties very different from the bulk liquids, these they regard as thick adsorbed films.

Taking into account the ellipticity of the earth, Dr. Harold Jaffreys has redetermined a large number of epicentres of Pacific earthquakes, and finds great improvement in the reliability of Pacific seismological stations.

Further experiments by Dr. T. F. Wall on the influence of surface treatment on magnetic properties show that nickel wires, heated in hydrogen and then cooled (for low values of the magnetic field strength), the greater the ratio of the surface perimeter to the cross sectional area, that is, the smaller the diameter, the less easily magnetized they are. An increase in the coercive force and in the remanence is likewise observed as the diameter decreases.

W. O. Williamson directs attention to the reversible darkening of some commercial titanium dioxide under the influence of light, and indicates a number of possible explanations.

A new crystal form of resorcinol is described by A. R. Ubbelohde and Dr. J. Montearth Robertson. This resembles the beta form of the tetradentoro-resorcinol crystals, and the authors suggest that there is a difference in the hydroxyl bonds in the two crystal forms, due to a difference in the intermolecular resonance.

The distance between the carbon and the halogen atoms in the methyl halides, recalculated from the spectroscopic data by Dr. G. B. B. M. Sutherland, are markedly smaller than the previously accepted ones and those obtained by the method of electron diffraction. The revised values appear the more likely to be correct on comparison with the corresponding distances in the carbon tetrahalides and with the force constants for the carbon-halogen bond in the two cases.

Prof. A. D. Peacock and Dr. Ann R. Sanderson find in the thelytokously parthenogenetic saw-fly, *Thrinax macula*, that the female chromosome constitution is $2n = 14$, that of the rare male (from second spermatocytes) $n = 7$, and that there is only one maturation division, non-reductional, in oogenesis. The work of Doncaster and of Comrie with other species of thelytokously parthenogenetic saw-flies shows two maturation divisions in oogenesis, and Peacock, Sanderson and Greenshields find that the female chromosome constitution in some 40 species of saw-flies is $2n = 16$. Accordingly, autoregulation of chromosome number in saw-flies is maintained by at least two methods, whilst *T. macula* is exceptional in its chromosome constitution.

Research Items

The Oolitic Limestone Escarpment in Bronze Age France

MISS MARGARET DUNLOP, in a study of the significance of the Oolitic limestone escarpment in the Bronze Age in France (*Man*, July 1937), points out that the grouping of Bronze Age finds in France is such that it is possible to discern three types of environment—maritime, riverine and plateau. In the cooler, wetter conditions of the Middle Bronze Age in the ninth century B.C. the forest-tree plateau, and the Oolitic limestone ridges in particular, are significant in the distribution of certain objects of material culture. They form a natural region imposing topographic restrictions on those using them, and may be said to be a distinct, though secondary, cultural province in the life of Bronze Age France and a feature of vital importance in the maintenance of exchange and some semblance of organization during the unsettled conditions of the Hallstatt phase of readjustment. The major Bronze and Early Iron Age cultural spreads affecting the French Oolite are as follows: c. 1750 B.C., an infiltration from the Rhine Valley and south Germany, characterized by the large broad triangular dagger and the flanged axe; (Jura, Dauphiné, down Rhone, etc.); c. 1400 B.C., invasion from south Germany and Bohemia—dagger with blade with two rivets, simple sword (Jura, Charente, south to Gard and Puy de Dome, tumuli of Côte d'Or and Jura, Herault); c. 1200 B.C., invasion and infiltration from north European plain—riveted pistilliform sword, winged lance with eyelet holes, terminal winged axe (Aube, Marne, S. Brittany); c. 850 B.C., first Hallstatt invasion from south Germany and western Austria—short bronze sword (Oolitic outcrop, eastern tumuli); c. 600 B.C., renewed invasions from same sources—iron sword with bronze rivets, hilt terminating in double circle (distributed as in previous period, concentration around iron mines of Châtillonais, north of Côte d'Or).

Extinct Mammals and Man in America

FURTHER evidence relating to the contemporary existence of man and an extinct mammalian fauna was obtained in pluvial deposits near Clovis, New Mexico, in the course of 1936. An account of the results of the work of the expedition, which was under the direction of Dr. E. B. Howard, acting on behalf of the Philadelphia Academy of Natural Sciences, has been prepared by Mr. John Lambert Cotter (*Proc. Acad. Nat. Sci. Philadelphia*, 89). The site under investigation was that known as "the gravel pit" in Blackwater Draw, between Portales and Clovis. The stratigraphy of the pit is characterized by the occurrence of three more or less distinct layers, aggregating approximately seven feet: first, brownish sand, extending two and a half feet from the surface; second, a bluish material containing sand, grit and clay, three feet; third, a speckled sand, one and a half feet thick. The blue stratum and the speckled sand were found to contain certain bone remains, with which were associated two Folsom-like points, a fragmentary point, a scraper, several flakes, all of

chalcodony, and two bone artefacts, such as have not previously been associated with a Folsom industry. The occurrence of the bones resolves itself into certain characteristics: the bones of the bison, except for a cannon bone and a scapula, occurred in the blue material immediately above the mammoth. The mammoth bones occupied the contact between the blue material and the speckled sand. Below the mammoth bones in the speckled sand were horse bones and traces of turtle-shells, thirteen inches below the contact of blue material and speckled sand. The lithic and bone artefacts were in definite association and contemporaneous with the mammoth bones. The bone artefacts show bevelled surfaces at their ends, which are compared with the splicing technique of the Eskimo and Indians of North America.

The Haemorrhagic States

THE haemorrhagic states were the subject of a discussion at a combined meeting of the Sections of Medicine and Pathology, Bacteriology and Immunology of the British Medical Association at its recent meeting in Belfast. Prof. L. J. Witts delivered the opening paper. He said that these conditions did not lend themselves to rigid classification. In the treatment of haemophilia, the local application of coagulant snake venoms was an important advance, but liver extract, oestrum and moccasin venom had been failures. For the idiopathic thrombocytopenic purpura removal of the spleen was the most successful treatment, but its mode of action was uncertain. Vitamin C was of value in scurvy only, and not in other haemorrhagic states. Dr. Capon discussed haemorrhagic conditions occurring occasionally in the newborn (about one in 400 cases) and found that the majority were relieved by an intramuscular injection of whole blood. Dr. Timperley maintained that an extract of egg-white, prepared by his special method, controlled internal haemorrhage in haemorrhagic states, but its efficiency was not confirmed by other speakers.

Grass-drying

SINCE the Agricultural Research Council issued its first report in 1935 on the preservation of grass and other fodder crops, much new information on the subject has been obtained and considerable advances made. While fewer than a dozen driers were in use in Great Britain during 1935, nearly fifty were at work in 1936. A survey of the problems connected with grass-drying and its effect on the economy and management of farms has been made by E. J. Roberts, and published as a report entitled "Grass Drying" to the Committee of the Council (London: H.M. Stationery Office. 2s. net). An introductory chapter describes the different methods of preserving grass, while others follow which deal with the extent of the grass-drying movement, the production of suitable herbage, the water content of the herbage,

cutting and hauling, furnaces, fuels and power, grass-drying machines and the feeding value of young grass. In the concluding chapter, the cost and profitableness of producing dried young grass are considered. Drying only becomes worth while if the special nutritive qualities of young grass can be conserved, and in wet seasons when growth is so rapid that the drier cannot deal with all the produce, definite areas should be devoted to hay-making or ensiling. The collection of short young grass originally offered some difficulty, but machines have now been devised which overcome this. The cost of production of dried grass in 1936 varied considerably on different farms; but the average figure, allowing for rent, overhead expenses and depreciation, was about £8 per ton, a figure which at the present price of concentrated feeding stuff allows a margin on true nutrient values. The chief obstacle to an extension of the process is the high capital cost of driers; but doubtless these will be lowered as experience is gained, and the enthusiasm shown both by the farmers and by the manufacturers of driers will go far to overcome the difficulties at present encountered.

The Soviet North Polar Station

REPORTS received in Moscow by radiogram from the floating observatory in the vicinity of the North Pole and supplied by the Soviet Union Year Book Press Service have already announced some results of interest. In lat. $88^{\circ} 54' N.$ long. $21^{\circ} W.$ the depth of the Arctic Ocean was found to be 2,345 fathoms (4,290 metres) and in lat. $88^{\circ} 47' N.$, long. $10^{\circ} W.$ 2,391 fathoms (4,374 metres). These readings compare with Peary's 1,500 fathoms (2,743 metres), no bottom, within five miles of the Pole and Amundsen's 2,050 fathoms (3,750 metres) in lat. $87^{\circ} 43' N.$, long. $10^{\circ} 21' W.$ Since the station is steadily drifting farther important soundings may be expected. In relation to Wilkins's sounding of 2,974 fathoms (5,440 metres) in lat. $77^{\circ} 45' N.$, long. $175^{\circ} W.$, it would appear that the deepest parts of the arctic basin occur in the Beaufort Sea and adjoining the wide Asiatic continental shelf. Another discovery of importance is the occurrence of a layer of water at a depth of 275–600 metres with a temperature above $0^{\circ} C.$ and a high salinity. This would appear to be the Atlantic water which Nansen discovered to be sinking, in the Spitsbergen area, below the colder and less saline polar water. Lastly, plankton determinations show a much more abundant pelagic life than had been anticipated.

Patterns of Proteins

In a recent paper (*Proc. Roy. Soc., A*, 160, 59; 1937), Dr. D. M. Wrinch presents a reasoned account of her theory of the molecular constitution of proteins. This is an attempt to provide a unitary explanation of three characters common to all soluble proteins: (a) The molecules are largely made up of amino- and imino-acid molecules. They contain peptide linkages but few free NH_2 groups. (b) There is a general uniformity among proteins of widely different chemical composition. (c) A large number of crystalline proteins have highly symmetrical crystals. These properties she claims to explain on the basis of higher order polymerization of amino-acids. The simple peptide link can only give rise to rings or chains of amino-acids. To get more complex aggregates it is necessary for each molecule to be linked to three or four others. This can be done by

an inner transformation according to the scheme:

On the basis of this transformation, it is possible to build up trigonal plane groups of different stages of complexity. These 'cyclol' sheets have, owing to the fact that all the amino-acids are of the α type—an observation which here, it is claimed, obtains significance for the first time—have all their side chains on one side of the plane. They can further be attached together either by means of these side groups or by hydroxyl bonds, thus forming larger aggregates, which must necessarily be integral multiples of the smallest of them, as Svedberg had found. Owing to their unsymmetrical character, such cyclol plates will be surface-active and the hypothetical structure gives a good agreement for the surface densities of protein films. Owing to the great complexity of protein chemistry, it may be long before it is possible to verify any of these hypotheses, but it must be admitted that the solution offered, although it contains arbitrary elements, is both simple and elegant.

Observation of a Fireball Train

In a recent paper (*J. Brit. Astro. Assoc.*, 47, 7; May 1937), Mr. M. A. Ellison describes a fireball observed on March 21 about $10^h 02^m$ U.T. The brightness was greater than that of Venus, and the colour was a golden-red. The most important point about this fireball was the velocity of the train. Mr. Ellison estimates that, at a height of 60 miles, the drift velocity was 133 miles per hour. From the configuration of the train, it is possible that the middle portion was subject to a current of even higher velocity than the ends. Many will be surprised at this velocity in the higher regions of the atmosphere, where it is believed that diffusion is a more potent factor in mixing the gases than currents of wind. If Mr. Ellison's figures be correct, it is obvious that the latter cannot be ignored in the stratosphere.

Aerodynamic and Electrodynamical Equations

N. P. KASTERN (Report of Academy of Sciences, U.S.S.R., December 9, 1936) has attempted to account for many phenomena, usually explained by relativity or quantum mechanics, on a strictly classical basis, merely by adding small extra terms to Maxwell's electrodynamical equations. At the same time he adds similar terms to Euler's equation of hydrodynamics, and unites these two sets of equations into a common system. It is claimed that the new hydrodynamic equations, as applied to vortex motion of gases (which is of great importance in aviation) explains several well-known phenomena inexplicable by the old equations. As for the new form of Maxwell's equations, the extra terms are non-linear, and involve a variable velocity of light. It is stated that the quantum properties of the field can be deduced from this basis. The grounds for this assertion are not fully explained, but they appear to be connected with an analogy between moving tubes of force and gaseous vortices.

Validity of Laws of Electrodynamics

IN the course of an investigation carried out for an electrical engineering company, I found that some generally accepted laws of electrodynamics were incorrect, and that serious mistakes were therefore being made by electrical engineers. As the laws here

Fig. 1.

referred to have been taught by such high authorities as Maxwell and Jeans, they are naturally being repeated in most of the text-books that are now used in our universities and technical colleges: in fact, none of these laws (which has already caused patents to be taken out for circuit breakers that will work in a very different way from what was expected, and for electric motors that will not work at all) is taught in all text-books that deal with the subject, including those used on the Continent and in America.

The law to which I have just referred is sometimes ascribed to Laplace, sometimes to Biot and Savart, sometimes to Ampère, and sometimes to Maxwell; but all teachers appear to regard that law as infallible. It may be stated as follows, though it is more frequently stated in a less complete form.

When a straight conductor element of length dx carries a current i in the OX direction of rectangular co-ordinates (right-handed) and lies in a magnetic field where the flux density has a component b in the OY direction, it is acted upon by a force $i.b.dx$ in the OZ direction.

The units here referred to are, of course, those of the c.g.s. system usually employed in text-books of electromagnetism. The current is accordingly in amperes and the force in dynes. In view of the doubt with regard to the name of the investigator by whom this law was first enunciated, I propose calling it 'the $i.b$ law'. This name seems appropriate, since the law says that $i.b$ is the force intensity (dynes per centimetre length of conductor) at the point in question.

But when the $i.b$ law is applied to the case shown in Fig. 1, which is a direct-view of a direct-current slip-ring dynamo designed by Dr. A. E. Clayton, it tells us that the machine will work, though Dr. Clayton found that it would not. From his description of the machine, in the *Electrician* of July 2, 1915, it appears that he may not have designed it with the idea that it would work, but with the

idea that its failure would disprove Faraday's law of electromagnetic induction. He evidently overlooked the fact that its failure has disproved the $i.b$ law; for he continued to teach this law, which is repeated in his latest books on dynamo design. But the following considerations will make it clear that the $i.b$ law has been conclusively disproved by the failure of this machine.

In Fig. 1, C, C, C, C are the ends of the straight iron cores upon which the field coils are wound, N is the ring-shaped north pole of the magnet, A is the ring-shaped core of the armature, and Y, Y, Y, Y are the ends of the straight iron yokes that connect this armature to a similar one at the south pole end and rotate with these armatures. All the rings here referred to were of rectangular cross-section, and the armatures were ring-wound on the parts between the yokes.

The machine should evidently work as a motor, according to the $i.b$ law, when the windings are suitably fed with direct current through the slip-rings; for the conductors that are in the main flux (between the armature cores and the magnet poles) should be subjected to a force much greater than any opposing force acting on conductors in the leakage flux, owing to the great permeance of the magnetic path in the iron yokes. Actually, however, the machine would not work; and this will be under-

Fig. 2.

stood when attention is directed to the fact that the amount of flux linking the winding would not begin to change when the armature began to rotate, with the consequence that (according to Neumann's law) no back-e.m.f. would be generated.

Dr. Clayton eventually came to the conclusion that his machine was a failure from every point of view: that is to say, it not only failed to work, but also (in his opinion) failed to give a disproof of Faraday's law. His present view is that Faraday's "lines of magnetic force" were rushing from yoke to yoke when the armature was rotating, cutting the inside conductors on their way, and thereby generating an e.m.f. that counterbalanced the one generated in the outer conductors. Many electrical engineers are unable to see any justification for this view; and Dr. Clayton will certainly find it useless as a defence of Faraday's law against the following argument.

Fig. 2 shows an experimental circuit-breaker arrangement, with mercury cups at *M* and *N* (where the arcs would be formed when the actual circuit breaker began to open). When this arrangement is surrounded by air, or by any other medium of unit permeability in the c.g.s. electromagnetic system, the amount of flux *dc* that is cut during a downward movement of *MBCN* through the distance *dy*, with the current kept constant, can be calculated by methods explained in text-books of electromagnetism. It will thus be found that *dc* consists of a part

$$2 i dy (0.054 + 0.161)$$

that comes from *MADN* and is cut by *BC*, and a part

$$2 i dy (0.054 + 0.030)$$

that comes from *MBCN* and is pulled across *AD*, so that

$$dc = 0.6 i dy.$$

According to Maxwell (see Art. 541 of his "Treatise on Electricity and Magnetism"), the total amount of flux-cutting must be equal to the total increase in the flux that links the electric circuit. But when we try to verify this in the present case, by making a direct calculation of the extra flux linkage *dk* that is due to the downward movement of *MBCN* through the distance *dy*, we get

$$dk = 17.5 i dy.$$

The great difference between *dc* and *dk* is accounted for by the fact that the stretching of *AB* and *DC* through the distance *dy* causes additional flux to be sent through the area *ABCD* by the added lengths *dy* at *M* and *N*.

If *MBCN* is moving downwards with a velocity of *v* centimetres per second, and if the movement through the distance *dy* takes place in the time *dt*, we have *dy/dt* = *v*, *dc/dt* = 0.6 *i v*, and *dk/dt* = 17.5 *i v*. The induced e.m.f. will therefore be 0.6 *i v* or 17.5 *i v*, according to whether Faraday's law or Neumann's law is correct. To settle this question, I attached *MBCN* to one end of a strip of wood that was arranged to turn about a knife-edge in the manner of the beam of a balance. This enabled me to measure the electromagnetic force *F* exerted on *MBCN* when various currents (up to 1,300 amperes) were flowing in the circuit. The strip of wood was fastened to the middle of *BC*, and was at right angles to the plane of *ABCD* when in the position of equilibrium.

As will be seen from Maxwell's Art. 583 or my article in *World Power* of March 1932, the energy equation is either

$$F dy = \frac{1}{2} i dc \quad (1)$$

or

$$F dy = \frac{1}{2} i dk, \quad (2),$$

according to whether Faraday's law or Neumann's law is correct; and a measurement of *F* with any

given value of *i* will show whether (1) or (2) is the correct equation. In each of the numerous cases that were tried, with various ratios of *BM* to *BC* and of *BM* to *BA*, the measured force was in close agreement with equation (2), though it was frequently (as in the case of Fig. 2) between 20 and 30 times as great as the force indicated by equation (1).

It may therefore be concluded, not merely that there is sometimes a great difference between the *d* and *dk* that Maxwell thought to be identical, but also that Neumann's law is right and Faraday's is wrong. W. F. DUNTON.

DURING recent years the points raised by Mr Dunton in the above note have been discussed a considerable length in electrical journals. Indeed controversy over the laws of electromagnetic induction has flared up periodically during the last half century. About forty years ago Carl Hering devised a number of ingenious experiments to show that 'flux cutting' was the essential factor in the generation of electromotive force. Some twenty years later Blondel described in the *Electrician* an experiment in which the total flux linkage—as defined by the product of the flux and the number of turns—was reduced from a large value to zero without e.m.f. being induced in the circuit, his method being to unwind a coil which had been wound upon a cylindrical magnet. A few years prior to this, I had carried out a number of experiments in an attempt to establish discrepancies between the 'flux cutting' and the 'rate of change of flux' theories, and in the correspondence consequent upon the publication of Blondel's work I described one of the models I had made for the purpose.

This model is the one described above by Mr Dunton; before it was built it was anticipated that no e.m.f. would be generated in its winding, and its behaviour on test fulfilled those expectations. However, I finally concluded that the action of the model was in line with that of the slotted armature generators now universally used, and the result of my investigations was to lead me to conclude that the total amount of 'flux cutting' is always equal to the change in the flux linkages. In short, my conclusions were in agreement with Art. 541 of Maxwell's classic book.

The behaviour of the model as a motor was never considered, but it follows that if its behaviour as a generator is in line with the slotted armature machine such will also be the case for motor action. The action of motors with slotted armatures is well known, and it is also well known that the torque developed between stator and rotor is altogether greater than would correspond to the product of the current in the conductors and the flux density in the slot. In my opinion the model gave no evidence regarding the laws of electromagnetic induction and electrodynamic other than that long since available with slotted armature machines.

For the past few years, Mr. Dunton has, in a most energetic and far-reaching manner, challenged the validity of some of the commonly accepted laws. His work arises out of calculations connected with expanding circuits—such calculations being of particular importance in the design of circuit-breakers. One such example is given in Fig. 2 of Mr. Dunton's communication. Now the flux linked with a circuit may be changed in various ways, of which one (a) is by changing the current carried by the circuit, and

other (b) is by maintaining the current constant and expanding the circuit as indicated, for example,

Mr. Dunton's Fig. 2. To my mind, there is no essential difference between these two cases. Nothing to be gained by confusing the issue with mathematics, for the only real issue involved is the manner in which the magnetic field comes into being. If it is taken that the growth of the field in (a) is accompanied by a corresponding flux cutting it surely must follow that any new flux created in (b) also necessitates corresponding flux cutting.

Quoting now from Mr. Dunton's letter: "The net difference between dc [that is, the flux cutting] and dk [that is, the change in the flux linkages], accounted for by the fact that the stretching of B and DO through the distance dy causes additional x to be sent through the area $ABCD$ by the added paths dy at M and N ". From this it is evident that Mr. Dunton has not concerned himself with

how this additional flux comes into being, and if his interpretation of flux cutting be taken there is no flux cutting in case (a) above. It is my view, therefore, that Mr. Dunton's arrangements of expanding circuits give no evidence—in support or otherwise of the validity of Art. 541 of Maxwell's "Treatise on Electricity and Magnetism"—other than that presented by the case of simple circuits carrying changing currents.

The issue involved is, of course, one of pure physics. With the great developments that are taking place in atomic physics one can look forward to the time when physicists will wrest further secrets from Nature and give to electrical engineers a clearer conception of what is really happening in magnetic fields, and of the 'mechanism' by which E.M.F. is actually induced in a circuit. But at the moment I see no reason for abandoning existing conceptions.

A. E. CLAYTON.

The Carnegie Institution of Washington

THE report of the president of the Carnegie Institution of Washington for the year ending October 31, 1936, reviews the relationship of its existing policies to research, and examines some of their implications as well as giving a brief account of researches in progress (Washington, D.C.: Carnegie Institution, 1937). The Institution has so far limited itself largely to securing new data and to the organization of information relating to mathematical research, investigation of natural phenomena and to history. The value of science in terms of its contribution to meet human needs is shown in many ways, but the Institution has also been concerned with the ways in which science can be effectively utilized to deal with difficult human relations such as those represented by economics and government. These possibilities have been recognized with the assumption that the best method of procedure is by co-operation between the sociologist, economist, or student of government and representatives of sciences with closely allied methods or problems.

The Institution has endeavoured to secure the practical application of results of research, whether from the physical or biological sciences or in human issues, as in psychology, and the importance of bringing together, in appropriate organizations, scientific workers and engineers and students of social and economic problems, with a view to the utilization of new ideas and techniques, is stressed. Responsibility in this field rests in part upon the scientific worker, and it is essential that the possible influence of science upon thought, and in the development of techniques which influence modes of thought, could receive close attention. Even in international relations the cultural and economic significance of science should not be overlooked.

In the field of astronomical research the work of the Mount Wilson Observatory has reached a stage when the accumulation of data permits the formation of new patterns with new theories and new points of view. The appearance of a bright nova in the constellation of Lacerta on June 18, like that of Nova Perseus, has received careful study, while a super-

nova has been discovered in one of the extra-galactic nebulae of the Virgo cluster. An extensive preliminary survey has been made of the number and distribution of the extra-galactic nebulae corresponding to the Milky Way, and measurements of the red shift of remote nebulae have received intensive study. The Department of Terrestrial Magnetism, in addition to studies on the causes of fluctuations in the earth's field, has investigated the question of magnetic disturbances, including world-wide magnetic storms, as well as the relation of magnetism to atomic physics, in which field it has been shown that protons and neutrons are probably identical in every respect except that of electrical charge. The Geophysical Laboratory has investigated the equilibrium between crystalline minerals, usually silicates, and their melts, including the equilibria of rock-forming silicates at atmospheric pressure, and has been responsible for a series of determinations of the radium content of samples obtained from the ocean-bottom.

Important seismological research has been carried out at Pasadena, and the Division of Plant Biology has been responsible for intensive studies of individual functions and components of plants as well as in photosynthesis, including the carotenoid pigments and the absorption of carbon dioxide by the unilluminated leaf. The work of the Division of Animal Biology has been characterized by increasing co-operation with other groups. Definite evidence has been obtained concerning factors involved in the origin of tumours. Much light has been thrown upon the development of the layers which are defined in early stages of the embryo, and studies in endocrinology have been concerned with the influence of prolactin, and the milk-producing hormone.

Other important studies have been concerned with genetics and nutrition, while the Division of Historical Research has concentrated attack on the early history of the Maya and major questions relating to the advance of civilization which have emphasized the value of data from other civilizations for testing modes of life and growth of an advancing civilization.

Fourth International Grassland Congress

THE paper-reading sessions of the fourth International Grassland Congress were held at Aberystwyth on July 14-18, under the presidency of Prof. R. G. Stapledon. A preliminary tour was arranged from Oxford through Leicestershire, the Cotswolds, Herefordshire and central Wales; a party of two hundred delegates left Oxford on July 10 and arrived in Aberystwyth on July 14. Delegates who participated in this tour had excellent opportunities of studying the modern developments in English grassland farming, such as the use and production of pedigree seed, artificial drying of grass, etc., and were therefore in a better position to appreciate the papers read afterwards by British specialists at the Aberystwyth meeting.

The numerous papers offered for presentation to the Congress were divided among plenary and sectional sessions. The plenary papers were divided into three groups, dealing with nutritional questions, herbage plant breeding and general grassland respectively. The sectional sessions, held on July 16, covered the six subdivisions of grassland research, namely, (1) grassland ecology, (2) seed mixtures, (3) plant breeding and seed production, (4) manures and fertilizers, (5) nutritive value of pastures and fodder conservation, and (6) management, yields and economics of pastures.

The subject-matter of the papers read is perhaps best dealt with according to country; this Congress differed in scope from its three predecessors, held in Germany, Scandinavia and Switzerland respectively, as the 450 delegates came from thirty-seven countries in all parts of the world, and were therefore interested in more varied aspects of the grassland problem than at the earlier conferences.

The British papers were concerned chiefly with the breeding of pure-bred grasses and clovers (T. J. Jenkin and R. D. Williams, Aberystwyth), the production and marketing of seed of pure-bred strains (T. E. Miln, Warrington, and Gwilym Evans, Aberystwyth), the use of lime and phosphate in grassland improvement (J. A. Hanley, Newcastle, and R. G. Heddlie and W. G. Ogg, Edinburgh and Aberdeen), the production and nutritive value of artificially dried grass (H. E. Woodman, Cambridge, and E. J. Roberts) and the economics of grassland improvement (John Orr, Manchester).

An important European paper was that delivered by A. I. Virtanen, Finland, on the associated growth of legumes and non-legumes; the old-established fact that non-legumes benefit by an association with legumes has been explained by recent work in his laboratory at Helsinki. Exact work with sterile culture technique has conclusively shown that nitrogenous compounds are excreted into the soil from legume nodules, and that this excretion commences immediately upon the formation of nodules. The excreted nitrogen compounds are products of nitrogen fixation and not decomposition products of proteins; the excretion products have been studied in an attempt to shed light on the mechanism of nitrogen fixation. The excretion is apparently an equilibrium reaction. Excretion of amino-acids has been demonstrated with all legumes so far examined (different species of clover, peas and lucerne). Application of nitrate appears to lower markedly the excretion.

A wide range of topics was covered by readers from other European countries. The Scandinavian countries have always been in the forefront as regards breeding of herbage plants; they were here represented by N. Sylván and H. Osvald, Sweden, and O. Valle, Finland. C. K. van Dealen, Holland, also stressed the importance of using indigenous or pure bred seed when sowing down pastures.

Papers on the grasslands of Hungary, read by K. T. Kolbai and J. von Pukovich, indicated the rapidly increasing interest in the subject in this country, where there are now three grassland unions with 60,000 farmer members. Another paper from the same country, by N. von Bittera, dealt with the peculiar problems of applying fertilizers to arid grassland, a subject of direct importance to the delegates from North America, Africa and Australia.

The profitability of applying nitrogenous fertilizers was discussed by readers from Sweden, Holland and Germany, the conservation of grassland herbage in the form of silage by delegates from Great Britain, Switzerland and Germany, and the good effect of alpine pasturing upon the health of stock by V. Venzani and E. Carbone of Italy. One of the leading grassland experts from Germany, E. Klapp of Bonn compared the effects of mowing and grazing upon pastures in general and upon certain herbage grasses and legumes in particular.

The outstanding value of pastures in erosion control has been an important factor in the rapid growth of pasture research in the United States and Canada in recent years. It was therefore not surprising that these two countries should be well represented at the Congress; the American delegation, under its chairman, P. V. Cardon, principal agronomist in charge, Division of Forage Crops and Disease Bureau of Plant Industry, U.S. Department of Agriculture, numbered fifty persons, the majority of whom were travelling in one party under the guidance of Dr. D. B. Johnstone-Wallace, Cornell University, on a tour of centres of grassland and scenic interest in Great Britain, Scandinavia, Germany, Austria, Switzerland and France.

Papers representing the current American outlook were read by three members of the U.S. Department of Agriculture, namely, P. V. Cardon (Bureau of Plant Industry), W. R. Chapline (U.S. Forest Service) and C. R. Enlow (Soil Conservation Service), who dealt respectively with the new herbage plant breeding programme, the revegetation and rehabilitation of the range lands of the western States and the value of pastures in erosion control. D. B. Johnstone-Wallace described his experiments with wild white clover at Cornell University in New York State which have been attracting so much attention in recent years among the pasture agronomists working in the more humid parts of the eastern United States.

L. E. Kirk discussed the herbage plant breeding problems of eastern and western Canada, while O. McConkey directed attention to the serious mineral deficiencies in the pastures of eastern Canada.

H. R. Marston presented in scientific terms the Australian sheep farmers' argument that "sow pastures ruin the wool" of the merino sheep. Improvement of the nutritional level of a pasture from

ie which has seriously handicapped production will rtainly affect the quality (fineness) of the fleece, it this change may just as certainly be made, if ed be, by the alteration of the type of sheep used r wool-growing on these areas. Small-framed, neely covered breeds of merinos which have been lected to produce fine wool when grazed on richer eas are well known.

E. Bruce Levy described the conversion of rain rest to grassland in New Zealand; the forests inverted are mainly of two types: rain forest roprier and sub-antarctic southern beech forest. The ages of the conversion to the famous pastures of ew Zealand were described in full, particular credit eing given to the pioneer back-country bush settlers.

A similar topic was discussed by G. H. Holford, New ealand, who illustrated his talk with a colour film.

The changing agricultural outlook in South Africa, ulting from the ravages of soil erosion, was ecribed by the representative of the South African epartment of Agriculture, J. W. Rowland. A re-ientation of the principles of arid land farming ust come about, governed by a full consideration

of the land, in the light of the complex inter-relationship between the soil, the plant and the climate.

The Congress ended with a tour through Northumberland to Edinburgh, when a day was spent in the Central Highlands of Scotland and the Trossachs.

The report of the Fourth Congress, containing the full text of all papers read, together with their English and German abstracts, will be published in October or November of this year, price £2 per copy. A volume containing the abstracts only (in English and German) is now available, price 5s., and may be obtained from the joint Secretaries, Fourth International Grassland Congress, Aberystwyth.

At the general meeting of the International Grassland Congress Association on July 16, Dr. D. S. Huisinga of the Netherlands repeated the invitation, already given at the Third Congress at Zürich, to hold the Fifth Congress in the Netherlands in 1940. The invitation was gratefully accepted, and Dr. Huisinga was elected president of the Fifth Congress. The Association was invited by Count Teleki of Hungary to hold its sixth meeting in that country in 1943.

Geology of Jersey

THE claims of Jersey in the Channel Islands as a field of research for British geologists and as a most suitable locality for field classes for students as more than once been urged. The chief reason why Jersey is not more widely used for the latter purpose, in spite of its undoubted attractions, is the lack of a modern complete connected account of the geology of the island.

In September 1934, the Geological and Mineralogical Society of Brittany visited the island under the direction of A. J. Robinson and A. E. Mourant. The report of the excursion has recently been published as a memoir of the Society¹, and should prove invaluable to geologists intending to visit Jersey. The work is in French; but it is typical scientific French, and the writers clearly realized that many of its readers would be English-speaking. Probably for this reason, the work of those English geologists who established the succession and relationships of the rock groups of Jersey is barely mentioned. In justice to them, however, it should be stated that the relationships described by Wells and Wooldridge² are accepted by the writers of the memoir, with one exception; they claim that no important break occurs between the St. Lo shales and the volcanic group.

A broad outline of the geology of Jersey is condensed into the first few pages, while the rest of the rest part of the memoir is taken up by a detailed day-by-day account of the excursion. The memoir, however, much more than a mere itinerary: it includes discussions of the many problems of age and old relations which still await complete solution. It has the commonly-accepted view that the lavas are of Pre-Cambrian age and probably to be correlated with the Uriconian volcanic rocks of Britain, re-examined in the light of a careful comparison between the Jersey lavas and those of the mainland of Brittany, and in view of the claim strongly urged by M. Y. Milon, of the University of Rennes, that the lavas of Paimpol are of Carboniferous, not Pre-Cambrian, age.

M. Milon himself contributes interesting "Notes and Observations on the Geology of Jersey and Armorica". In particular, the age and conditions of accumulation of the Rozel conglomerate group are discussed, and it is concluded that these rocks, so strikingly similar to the Permian breccio-conglomerates of eastern Devonshire, were deposited on the borders of a Permian-Triassic cuvette, under 'continental' conditions.

In addition to the solid geology, the Pleistocene deposits, the raised beaches and the caves are adequately described by M. A. Bigot in the second part of the memoir.

Although natural inland outcrops are few in Jersey, the island provides a magnificent series of coastal exposures in the cliffs and extensive wave-cut platforms. In the main, these exposures are not difficult of access; but the casual visitor is liable to disappointment unless the tides are studied and the routes so chosen as to take full advantage of the periods of low water. With commendable foresight, the authors recommend in the introduction that the conditions are most favourable during the period comprising the three days before new or full moon and the five days which follow. The authors are resident in Jersey, and their detailed local knowledge has ensured that in the course of the five journeys described the time would be used to the best advantage and the maximum of geology would be seen. Each route is clearly shown on a sketch-map, with localities numbered to correspond with the text. For those with more time at their disposal, additional excursions are suggested.

Among the nineteen figures included in the text are several geological sketch-maps on a generous scale, while a folding geological map on the scale of 1:50,000 and five plates are incorporated.

Science News a Century Ago

The Entomological Society

At a meeting of the Entomological Society held on August 7, 1837, Mr. Bowerbank exhibited specimens of cork infused by termites while on board ship, and suggested measures to prevent attack by such insects; Mr. Bambridge spoke of the damage to apple trees in the neighbourhood of Lambeth by a small species of moth; and Mr. Westwood gave an account of an entomological visit he had lately made to Paris, noticing among other things a disease called muscadine with which silkworms had been very extensively attacked in France. The malady was a parasite which gradually enveloped the whole body in a white fungus and destroyed the worm, the mischief being produced by the explosion of a fungus, which is taken in by the spiracles or pores of the skin, as has been proved by M. Audouin, who has inoculated several worms and beetles with it. In concluding, Mr. Westwood made some remarks on the progress of entomology in France, which he stated to be in advance of Great Britain, there being more working cultivators, and the collection at the Jardin des Plantes being superior to that at the British Museum; M. Audouin had just completed a course of fifty lectures on entomology.

Bradley's Zenith Sector sent to the Cape

WHEN Malear became Astronomer Royal at the Cape of Good Hope in 1833, one of his first tasks was to re-measure and extend the arc of meridian measured by the French astronomer Lacaille in 1752. To further this work, Airy, on February 24, 1837, wrote to Captain Beaufort, the hydrographer at the Admiralty, suggesting that Bradley's sector then at Greenwich should be used for verifying the astronomical determinations. The Admiralty agreed to the suggestion, the sector was re-mounted, careful drawings were made of every part, instructions were prepared for its use, and on August 10 it was sent to Woolwich Dockyard and shipped for the Cape. Malear commenced his verifications of Lacaille's arc in 1838, between 1840 and 1847 the field work was accomplished, and the sector was returned to Greenwich in 1850.

The sector was originally made by George Graham for Bradley in 1727. It had a radius of $12\frac{1}{2}$ ft. and a range of $12\frac{1}{2}^\circ$. It was mounted by Bradley at his aunt's house at Wanstead, and it was from observations made with it that he was led to the discovery of aberration and nutation. In 1742, Bradley succeeded Halley as Astronomer Royal, and in 1749 the sector was removed to Greenwich. It is now preserved with other historic instruments at the Royal Observatory.

Sir Thomas Malear, who was born in 1794 and died in 1879, was director of the Cape Observatory until 1870. He was knighted in 1860, and for his geodetical work received the Lalande Medal of the Paris Academy of Sciences and a Royal Medal of the Royal Society. He is buried in the grounds of the Observatory.

Magneto-Electric Currents

"M. AUGUSTE DE LA RIVE has been studying the properties of magneto-electric currents, and among other results he finds that the helix of a metallic

thermometer heats to 7° when there are but 1 currents alternating contrary every second; to with nine currents; to 100° with twenty currents and to 133° with forty currents; and that a wire of platinum has been heated red-hot when a succession of currents have been even more rapid. Chemical effects are subject to the same influence only that there is a limit at which the heat of decomposition slackens. The influence of this speed is a felt in physiological processes, which acquire more greater energy than when produced by voltaic currents; a phenomenon which may be attributed to the interruption and alternatively contrary direct of magneto-electric currents, and which, perhaps may become advantageous in the practice of medical art" (*Athenaeum*, Aug. 12, 1837).

Typhoid and Typhus Fevers

THE issue of the *American Journal of Medical Sciences* of August 1837 contains the first clear distinction between typhoid (dothineritis) and typhus fevers. The writer was Dr. W. W. Gerha, physician to the Philadelphia Hospital, Blockley, a his paper was entitled "On the Typhus Fever which occurred at Philadelphia in the Spring and Summer of 1836". The principal differences between the two diseases are summed up as follows: "Dothineritis is usually a sporadic disease, although it sometimes appears to be a widespread epidemic. In the latter case the symptoms are so well marked that they are never doubtful except in a few of the earliest examples. Now typhus is rarely sporadic, and scattering cases do occur, they are generally connected with an epidemic and follow it. . . . (2) Typhus is evidently very contagious; in the epidemic of 1836 it is quite as contagious as small-pox. . . . Dothineritis is certainly not contagious under ordinary circumstances, although in some epidemics we have striking reason to believe that it becomes so. (3) The initial symptoms of the two affections chiefly differ in the greater stupor, dullness and prostration of typhus, which are in strong contrast to the moderate cephalalgia and disturbance of the senses in dothineritis. . . . When the disease is completely formed, the characters on which the distinction between the two forms of fever rest are: (1) The suffusion of the eyes, which occurs in every case, nearly every case of typhus fever, with the dusky red aspect of the countenance. (2) The extreme stupor and inactivity of the mind, even when positive delirium does not exist. (3) We also observe typhus no constant abdominal symptoms, and first merely dullness on percussion and feebleness of respiration at the posterior surface of the lungs. To these symptoms be added the peculiar eruption of petechiae which is scarcely ever absent in white there remains hardly a possibility of error."

A Female Rhinoceros in the Zoo

THE August issue (No. 59) 1837 of *Neue Notizen aus dem Gebiete der Natur- und Heilkunde* contains the following announcement: "A female rhinoceros in the garden of the Zoological Society of London the latest and most interesting acquisition which this menagerie has made. It is a very fine young animal, but only half the size of the male rhinoceros which has been in the possession of the Society for several years. This is the first time, so far as we know, that a rhinoceros pair (male and female) has been exhibited at the same time in Europe."

Societies and Academies

Dublin

Royal Irish Academy, May 31

J. J. HARTLEY: The Dalradian rocks of the Sperrin Mountains. The paper dealt with the Dalradian sequence as developed on the borders of Counties Derry and Tyrone in Northern Ireland. The stratigraphical succession was described, and a detailed correlation suggested with Kintyre and Corval in south-west Scotland. Attention was directed to the influence the important faults which traverse the area have upon the structure and the light which they throw on the character of the folding. The question of the metamorphism was briefly discussed.

J. KAYE CHARLESWORTH: A map of the glacier lakes and local glaciers of the Wicklow Hills. This portrays the distribution of the local glaciers (in the main after A. Farrington) and of nine chains of glacier lakes impounded by the extraneous ice on either side of the Wicklow Hills.

K. G. EMILJUS, E. B. CATHOART and C. M. MINNIS: Some electrical and optical properties of iodine vapour. The intensity distribution and absolute intensity in the iodine atom electron affinity spectrum have been calculated for typical discharge conditions from the results of probe analysis and theoretical capture cross-sections. The main part of the spectrum is usually in the far ultra-violet. The intensity in the near ultra-violet is so small as probably to preclude its observation. A high-frequency discharge with a constricted positive column is described which is of interest in connexion with the mechanism of the positive column. The effect of formation of negative ions in hindering removal of impurities by the discharge is pointed out.

Paris

Academy of Sciences, June 7 (C.R., 204, 1693-1768).

HYACINTHE VINCENT: The antitoxic power of glutathione on the diphtheritic and tetanic toxins. Glutathione shows a slight but distinct antitoxic power towards the toxin of diphtheria.

ANDRÉ BLONDEL: The experimental study of coloured signals intended for navigation.

WOLFGANG DEBLIN and ROBERT FORTET: On two notes of Kryloff and Bogoliouboff.

W. STERODZINSKI: A class of surfaces of affine space.

HENRI DULAC: Research on limit cycles.

DRAGOSLAV S. MITRINOVITCH: A differential equation of the first order occurring in various problems of geometry.

ANDRÉ MACHIEUX: Concerning a criterion of the reality of the velocities of nebulae. Criticism of the method of E. Hubble based on spectroscopic and photometric data.

GÉRARD PÉLIAU: The matrix representation of the Maxwell equations.

GEORGES ALBERT BOUTRY and GEORGES TRÉFOUIL: Commutable and stable electrical contacts. The variation in the resistance of sliding or plug contacts is too large for use in high-precision electrical thermometry. A new form of contact is described (mercury-platinum in a vacuum) giving resistances constant to within two microhms.

OLIG YADOFF: The electrical and mechanical ageing of copper conductors under the prolonged action of the electric current. Prolonged passage of

current (two years) through copper conductors produces a loss in mechanical strength and a slight increase in the electrical conductivity.

ROBERT FORREY: The intensity of orbital interaction in compounds with multiple ionization.

GABRIEL BOSSCHUETER and JACQUES FERRIER: The infra-red absorption spectra of water, liquid, solid and in solution. Comparison of the infra-red spectra of water in the liquid and in ice with solutions in carbon tetrachloride and carbon bisulphide.

MILIE. DINAH BIQUARD: The Raman spectra of some ketones. The influence of ring formation.

STANISLAW ROUPPERT: The action of the magnetic field on the absorption of selenium.

AUGUSTE ROUSSET: New measurements of the factor of depolarization of light diffused by argon. Improvements in the construction of the apparatus lead to a factor of depolarization for argon equal to 3×10^{-4} with incident parallel polarized light. The factor is certainly below 10^{-3} .

SALOMON ROSENBLUM and MARCEL GUILLOT: The γ spectrum of RaB and RdAc.

PIERRE BARCHEWITZ and RENÉ FREYMANN: The complexity of the (OH) infra-red absorption bands.

JOSEPH LAISSUS: The cementation of nickel by beryllium. The Brinell hardness of nickel cemented by beryllium is one of the highest determined on metallurgical products.

MARCEL PRÉVIER: The heterogeneous combustion of mixtures of carbon monoxide, hydrogen and oxygen on a vitreous surface. The heterogeneous combustion of most mixtures of hydrogen, carbon monoxide and oxygen is controlled by the velocity of oxidation of the hydrogen.

ANDRÉ CHRISTEN and JEAN KRAFT: The uranyl phosphites. The sole product of the interaction of solutions of phosphorous acid and uranyl acetate is a neutral uranyl phosphite, $\text{UO}_2\text{HPO}_3 \cdot 2\text{H}_2\text{O}$.

MILIE. SUZANNE HÉMAR: The precipitation in the cold of a copper salt by an alkaline carbonate.

HENRI GUÉRIN: The magnesium arsenates.

H. CLÉMENT and J. SAVARD: The halide of pentamethylmagnesium.

LOUIS LONGCHAMON: The dehydration of coals.

HELGE G. BACKLUND: Some eruptive rocks of the basalt series from the eastern coast of Greenland.

HENRI HUMBERT: *Gentianothamnus*, a new genus of Gentianaceae from Madagascar.

ROBERT WHILL: The existence of a monoconidome in the medusoid of a polypus (*Pennaria(?) tiarella*) with tetraconidome.

ERNEST KAHANE and MILIE. JEANNE-LÉVY: The mechanism of the sensitization with acetylcholine.

MILIE. ÉTIENNETTE BIZET and RAYMOND-HALLET: The opposed effects of two alkaloids from the same vegetable drug.

ÉMILE F. TERBOINE, MILIE. A. M. DE LA BERNARDIN and PAUL LÉLU: Action of the external temperature on the metabolism of creatinine and creatine.

ANDRÉ BOIVIN and MME. LYDIA MÈREBEAU: The existence of a thermo-labile toxin and neurotope (exotoxine) in the bacterial bodies of the Shiga bacillus.

LÉON BINET, CHARLES JAULMES and GEORGES WELLES: The antitoxic power of glutathione. Researches on the tetanus toxin.

ERNEST FOURNIAU, JACQUES TRÉFOUIL, FEDERICO NITTI, DANIEL BOVET and MME. JACQUES TRÉFOUIL: The anti-streptococcal action of organic sulphur derivatives.

Moscow

Academy of Sciences, *C.R.*, 15, No. 1; 1937.

N. S. KOŠLIakov: A transformation of definite integrals and its application to the theory of Riemann's function $\zeta(s)$.

E. LIUSTICH: Some methods for mechanical integrators.

V. G. ČILIDZE: The derived numbers of a function of two variables.

V. NIEMYTZKI: (1) The integral non-linear equations comparable to the linear equations. (2) The most generalized integral non-linear equation.

N. PIKUNOV: The limit problem for an equation with partial derivatives of hyperbolic-parabolic type.

E. J. PIREPELIKIN: An apparatus for quick and accurate reduction of self-registering micro-photometer records.

A. A. ŠIŠLOVSKIY: A comparison of absorption and fluorescence spectra of anthracene in different states of aggregation.

F. A. KOBOLEV: The application of Toeplitz's method to measuring the absorption of ultra-sounds in liquids.

K. G. MIKHUŠ: Side processes of oxidation during the reduction of nitrogen compounds of the aromatic series (2). Action of a bivalent iron salt on aryl-hydroxylamines.

I. B. PLIŠAKOV: The stratigraphy of the Tertiary oil-bearing beds of the south-eastern part of the Soviet Sakhalin.

A. G. EBBEIN: The Pontic rocks of Mingrelia.

I. A. SMORODINCHV, N. N. KBYLOVA and V. I. PASONINA: Changes of protein fractions in meat ripening.

V. A. NOVILOV: Derangement of metabolism in the leaves of lucerne when infected with the rust *Uromyces striatus* Schröt.

N. DRAGOMIROV: (1) Experimental induction of retina in amphibian embryos. (2) Influence of the adjoining ectoderm on the organization of the eye bud.

Vienna

Academy of Sciences, May 13.

BERTA KARLIK and KARL PREIBRAM: Infra-red luminescence spectrum of samarium. The spectrum found by Tomaschek is ascribed to divalent samarium.

MARISTTA BLAU and HERIETHA WAMBACHER: Measurement of the length of proton tracks by the photographic method. A few tracks have been recorded of protons liberated by neutrons from a polonium-beryllium source and of a length corresponding to an energy of between 7.9 and 10 million electron volts. The percentage of these high-energy neutrons is determined.

MARGARETHE HOLUBA: Influence of absorption in the interior of a radioactive preparation on the emitted radiation.

K. W. F. KOHLRAUSCH and R. SKRABAL: Studies of the Raman effect (71). Cyclopropane carboxylic acid, acrylic acid and their derivatives.

A. W. RHITZ and R. SKRABAL: Studies of the Raman effect (72). Nitrogenous bodies (4). Nitriles.

S. FRIEDLBERG and H. LAMPEL: Determination of the point of attack of drugs affecting the brain by measurement of the heat developed in different parts of the brain.

KLAUS UNNA and LEOPOLD WALTERSKIRCHEN: Influence of pituitrin on the action of some diuretics.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

JUNIOR SCIENTIFIC OFFICERS in the Electricity, Radio and Aerodynamics Departments of the National Physical Laboratory, Teddington—The Director (August 9).

LECTURER IN MECHANICAL ENGINEERING in the Batley Technical College—The Director of Education, Education Office, Batley (August 14).

ASSISTANT (grade II—engineering) in the Admiralty Technical Pool—The Secretary of the Admiralty (O.R. Branch) (August 16).

TWO DEMONSTRATORS IN INORGANIC CHEMISTRY in the University of Leeds—The Registrar (August 23).

JUNIOR LECTURER IN MYCOLOGY in the Imperial College of Tropical Agriculture, Trinidad—The Secretary, 14 Trinity Square, London E.C.3 (August 31).

ASSISTANT LECTURER IN MATHEMATICS in the University of Manchester—The Registrar (September 1).

ASTRONOMER ROYAL FOR SCOTLAND AND PROFESSOR OF ASTRONOMY in the University of Edinburgh—The Private Secretary, Scottish Office, Whitehall, S.W.1 (September 18).

UNIVERSITY PROFESSOR OF PHARMACOLOGY in the College of the Pharmaceutical Society of Great Britain—The Academic Registrar, University of London, W.C.1 (September 14).

UNIVERSITY READER IN BACTERIOLOGY in the British Postgraduate Medical School—The Academic Registrar, University of London, W.C.1 (September 15).

ASSISTANT LECTURER IN MECHANICAL ENGINEERING in the Manchester Municipal College of Technology—The Registrar (September 20).

METALLURGIST, ENGINEER OR CHEMIST for the Mond Nickel Co.—The Manager, Research and Development Dept., The Mond Nickel Co., Ltd., Thames House, Millbank, S.W.1.

TECHNICAL ASSISTANT in the Information Department of the Automobile Research Laboratories—I.A.R., Research Department Great West Road, Brentford, Middlesex.

Vol. 140

Science in Social Services

IN his farewell address on June 24 to the London School of Economics, Sir William Beveridge emphasized the need for both observation and detachment in the social sciences. Failure to be scientific in method and detachment on the part of both economists and statesmen, he said, had largely been responsible for the tardy development or recognition of the social sciences, alike in the neglect of observation of facts as the basis of theories and as the control of theories, and in the lack of detachment from partisan actions and the giving of judgment on controversial political issues. The social services of Great Britain might well have been cited by Sir William Beveridge to illustrate his point. They continue to grow piecemeal, and every session Parliament adds something to the imposing structure; but it is nearly thirty years since the last comprehensive inquiry into public social provision in Great Britain was made. Continually, however, we witness particular aspects of the social services criticized strongly to prove or disprove some political tenet or preconceived idea, and it is rare indeed to find them considered in relation to a comprehensive and well-defined social policy.

The report on the social services which has just been issued by P.E.P. (Political and Economic Planning) accordingly meets a definite need as well as provides a noteworthy example of the type of impartial and comprehensive analysis of the facts desiderated by Sir William Beveridge. The report has the freedom from preconceptions which characterizes the investigations of P.E.P. and gives us a comprehensive and detailed examination of each of the social services.

With some of these individual social services, which are grouped in three categories—namely, constructive community services, such as education and public health and the employment exchanges; social insurance services, such as national health insurance, unemployment insurance, widows', orphans' and old-age contributory pensions, as well as workmen's compensation; and social assistance services, such as non-contributory old-age pensions, unemployment and public assistance—scientific workers may have their own particular contact as individual citizens. With the collective review of the services as a system, the mapping of the ground they cover, and the intervening gaps, as well as with the indications which this report affords of trends in policy which are not yet fully developed in the existing social services, scientific workers will, however, have a keen, if not a professional, interest.

The admirable survey and analysis which are provided in this report are primarily a stimulus to further constructive thinking; and opinions in some matters that have sometimes ranked as established convictions will require re-examination by unprejudiced students. Despite the great increase in the last thirty years of expenditure on social services, which now reaches the sum of £400,000,000 a year, that is, nearly £9 a head, or about a tenth of the national income of 1934, 71 per cent of which is financed out of rates and taxes, the report shows clearly that there has been no spectacular transfer of wealth from rich to poor. Indirect taxation of the working classes has increased side-by-side with the direct taxation of the well-to-do.

The main argument of the report is not that we should begin to economize on our social services but that we should plan them better. At present they are the result of piecemeal political and administrative improvisations which need replacing by a more deliberate social service policy, a continued review with a programme of priorities and the filling of gaps. Many of these gaps, as well as serious anomalies and defects, wide disparities, and abuses, appearing unchecked in our present system, are duly pointed out in the report, which leaves no doubt of the room for reform. But the report does more than this. It assists the emergence of a mature philosophy and a broad strategy of the social services, and thus the replacement of fairly strong but largely unconscious tendency by conscious purpose.

This establishment of guiding principles, and of authority to ensure their observance in practice, is best secured not by a Royal Commission, which is regarded as too cumbersome, but by the establishment of a Social Service Statutory Committee, acting as an advisory general headquarters staff. The value of this type of detached examination and criticism is demonstrated by the experience of the Unemployment Insurance Statutory Committee and of the Law Revision Committee. The suggested committee would have three main duties: to study the basic principles of the services; to promote efficient and economic working, indicating any needful change of administrative and financial structure; and to direct attention to anomalies and gaps, making remedial proposals.

Scientific workers will be quick to recognize in this suggestion something of the ideas expounded by General Smuts in his Sidgwick Memorial Lecture on "Democracy"; and this further plea for an extension of scientific method and inquiry into controversial matters which should be settled on a basis of fact, and not prejudice, will be welcomed by them. Equally, too, the report makes clear the impossibility of isolating politically the social services. Economic policy, social service policy, and industrial wage policy are closely interlocked. Under our present health insurance system bad industrial organization may be persistently subsidized. The powers provided under the National Health Insurance Act to survey the health of local communities, and penalize employers responsible for high sickness rates, have never been used, and certain factories and offices continue to be so unsatisfactorily arranged or operated that

they give rise to excessive numbers of sickness claims.

The increasing part which scientific workers take in the administrative side of industry gives the special responsibilities in these matters, and the report also comments on the failure of those in charge of the great public social insurances of the United Kingdom to be alive to these questions and to take the broad view of their functions helping to reduce accidents and disease, which some private enterprise insurance companies have done. Dereliction of duty of this type is one of the prime concerns of associations of professional workers, and it is clear that such associations need much more general support from the rank and file of the professions and also continued stimulus. Their functions are to be fully and wisely discharged.

The clear thinking of this report, no less than its analysis of the facts, can scarcely fail to be highly suggestive to many scientific and professional workers and to stimulate further thought and effort in many fields. There are, however, other matters of immediate personal concern to scientific workers on which the report touches. For example, in its summing-up of the problems of the family, the report favours the introduction into the general wage and salary system of Great Britain of the principle of family allowances, which social reformers as well as industrialists have been largely opposed. The report argues that public social services must either consciously be used as an agency for adjusting burdens between large and small families, or else they will tend more and more to reinforce those commercial and other agencies which are steadily making life less attractive for the average citizen to rear a family.

A second matter raised by the report, which is also of direct concern to scientific workers, is that of the personnel of social service administration. On this subject it makes two main criticisms. The preparation of the report has revealed a serious amount of compartmental outlook and experience as characterizing those engaged in the administration of the social services at this stage. There are many men and women who are well informed about particular branches or aspects, but it is rare to find anyone who has given much thought to the inter-relations of the social services with one another, or to their repercussions on social or economic life and to their lines of development.

One of the first needs of to-day is the breakdown of this sectionalism and departmentalism; those concerned with particular aspects or subjects should start thinking intensively about the place of their own specialism in the whole scheme of the social services. In part, this is a matter in which professional associations could exert a useful influence, and their direct contribution to the effective co-ordination of the social services with one another, and with national policy as a whole, or to the re-examination of the forms of democratic control and public accountability in the social services, should not be negligible. In part, however, it is a matter of recruitment, and here the report refers to the failure to implement the recommendations of the Departmental Committee on the Recruitment and Training of Local Government Officers, in its report issued in 1935.

The need for improved recruitment and training is not, however, confined to the local government service. Although the quality of the personnel is often of the highest order, existing arrangements for the recruitment and training of officers for certain forms of social work, for example, the work of the Unemployment Assistance Board, are not entirely satisfactory. Apart from the importance of recruiting officers for the social services whose training and outlook raises them above departmentalism and stimulates constructive thought

about the place of their special work in the social services and policy generally, the formal training requirements of various departments or branches of the service are very narrow and overweighted by technical questions arising out of statutes, regulations and codes of instructions.

The report suggests that there is a real need for a comprehensive course of training in social case work to be taken by all who wish to engage in this career; and it is clear that, in this matter also, professional associations could offer a very useful contribution. Moreover, the report shows that there are very important spheres of social service in which, whether because of their experimental or controversial nature at the time, the exceptional freedom of opinion and experiment demanded for teaching or research, or the individual attention required for intimate personal problems, voluntary organizations are not only more appropriate but also may have essential functions to fulfil.

At a time when scientific workers generally are considering so closely the social consequences of their work, the PEP report not only provides a very stimulating survey of the field which indicates definite directions for further research, but also issues a challenge to really practical efforts which can scarcely be ignored by such workers if their interest in social affairs and social science is sincere.

History of Elementary Mathematics

Geschichte der Elementar-Mathematik in systematischer Darstellung:
mit besonderer Berücksichtigung der Fachwörter.
Von Dr. Johannes Tropicke. Band 3: Proportionen, Gleichungen. Dritte, verbesserte und vermehrte Auflage. Pp. iv+239. (Berlin und Leipzig: Walter de Gruyter und Co., 1937.) 10 gold marks.

ALL who are interested in the history of mathematics will be delighted to see that Dr. Tropicke continues to make progress with the publication of the third edition of this invaluable work which, in the form it took in the second edition, has long been an indispensable book of reference. It is nearly thirty-five years since the date of the preface to the first edition (summer 1902) in two volumes; the second edition, much enlarged and

modified in arrangement, came out in seven volumes or parts between the years 1920 and 1924, and grew to a compass of nearly 1,300 pages in all. The third edition, in consequence of the mass of fresh material which has accumulated since 1924 through new discoveries and researches, bids fair to show an increase in size of one third or thereabouts. It is gratifying to find that each volume as it comes out brings the subject of it up to date. There are many references in the present volume to books and papers of date so recent as 1936. Some slight inconvenience will be caused by the fact that, owing doubtless to the amount of work involved, the volumes are appearing at considerable intervals—vol. 1 appeared in 1930, vol. 2 in 1933, and vol. 3 in 1937—so that, as each volume comes out necessitating a multitude of fresh references, the references in the earlier volumes

also have to be added to or corrected. This disadvantage, however, is minimized by ingenious tables given at the end of each volume showing the correspondence of the pages in the second and third editions respectively, and the changes in the numbering of the various footnotes.

The subject of proportions takes up only one tenth of the volume, the other nine tenths being devoted to equations. This is because, with the gradual evolution of algebraical notation, the subject of proportions has come to occupy less and less space in original works and text-books. The Greeks, for example, had largely to use proportions and their transformations (by compounding, etc.) as a substitute for what we state and manipulate in the form of equations; in their 'geometrical algebra', this was the only means by which they could overcome the restriction of their work to not more than three dimensions. It was not until Heron's time that their treatment of equations became arithmetical enough to enable a number representing an area to be added to a number representing a length and so on, whereas the Babylonian, many centuries before, had done this without any hesitation. Beyond indications that the idea of ratio and proportion is found in Babylonian mathematics and in the Moscow Papyrus, the section on proportion shows little change from the second edition.

The history of equations is treated under the following heads: general historical survey, the distinction between the known and the unknown quantity, technical terms, equations of the first degree (a) with one unknown, (b) with more unknowns, equations of the second degree, 'reciprocal' equations, quadratic equations with more than one unknown, equations of the third degree and solutions of the same by algebra, geometry and trigonometry respectively, as well as solutions by approximation and by the method of 'false hypothesis' (*regula falsi*), equations of the fourth degree, equations of degree higher than the fourth, and lastly indeterminate equations including 'Diophantine analysis', etc.

The bulk of the new material which called for treatment in the new edition relates to mathematics before the time of the Greeks. Thanks to the new editions of the Rhind Papyrus by Peet and Chace respectively, to the publication by W. W. Struve of the Moscow Papyrus in 1930, and to the extensive discussion to which they have given rise, we are now in a much better position to judge of the scope of the ancient Egyptian mathematics. More important still, the publication by O. Neugebauer of Babylonian cuneiform texts of mathematical content going back to 1800 and 2000 B.C., and the books and papers that have been written upon them in recent years (by O. Neugebauer himself,

Kurt Vogel and others), have thrown a flood of light on the achievements of the Babylonians in arithmetic and algebra. It is now shown that the Babylonians of those early days consistently used and manipulated with ease the sexagesimal system of numeration (including the successive sexagesimal fractions) necessitating the use of multiplication tables going up to 59 times 59; they solved quadratic equations by steps precisely equivalent to the use of the regular formulae of our text-books though without any statement of a rule and with no better technical terms for the unknowns (which we call x , y , z , etc.) than the words 'length', 'breadth', 'depth' and such-like written in full. Some of their problems lead even to a type of cubic equation which can be put in the particular form $x^3 + x^2 = a$; one of these gives $x^3 + x^2 = 4, 12$ ($= 252$), and the solution $x = 6$ is merely stated, leaving us to speculate how it was arrived at, which would be a complete mystery but for the discovery of a table of sums of numbers of the form $n^3 + n^2$ for different values of n from 1 to 1,0 or 60. All these things are duly recorded in the volume before us, with very full references.

The dependence of the Greek solutions of quadratic equations on geometry, and ultimately on the discovery by the Pythagoreans of the method of 'application of areas', has long been known; but the specific connexion with propositions in Euclid (Book 2 generally and Props. 4, 5, 6 in particular, Book 6, 27-29, and Props. 84-86 of the "Data") is here treated at much greater length and much more fully elucidated with diagrams than it was in the earlier edition.

A word should be added about the appendixes. These include, besides the tables showing the correspondence between page numbers and note numbers in the third and second editions, three noteworthy features. (1) Chronological tables showing the gradual evolution of modern algebraical notation. (2) Original examples of the actual working-out of solutions of equations, from the Babylonians downward to Newton. These with their great variety of notations are fascinating to follow: there are seventy-two of them, and they include solutions by Al-Khwārizmī, Leonardo of Pisa, Regiomontanus, the authors of German and Latin MSS. of 1461 and 1481, Nic. Chuquet, Johan Widman, Luca Pacioli, Grammateus (Heinrich Schreiber), A. Riese, Christoff Rudolf, Michael Stifel, Cardano, Johannes Buteo, Bombelli, Stevin, van Schooten, Kepler, Harriot, Fermat, Descartes and Newton. (3) Solutions by means of conics of the cubic equations, $x^3 = a$, $x^3 + bx = a$ from Omar Khayyām's algebra.

The book cannot be too strongly recommended.

T. L. H.

Mechanism of Growth in Plants

Growth Hormones in Plants

Authorized English Translation of "Die Wuchstoffs-theorie und ihre Bedeutung für die Analyse des Wachstums und der Wachstumsbewegungen der Pflanzen". By Prof. Boysen Jensen. Translated and revised by George S. Avery, Jr. and Paul R. Burkholder, with the collaboration of Harriet B. Creighton and Beatrice A. Scheer. McGraw-Hill Publications in the Agricultural and Botanical Sciences. Pp. xiv+268. (London: McGraw-Hill Publishing Co., Ltd., 1936.) 21s.

THIS book is very necessary, and has been well done. During the last decade, no field of work has been more popular among students of plants; the output of papers has been enormous. The field is very adequately covered in this book, which also contains a very extensive bibliography.

Prof. Boysen Jensen's original experiments demonstrating the continued phototropic curvatures of the base of the coleoptile after its tip had been cut off and then replaced when only this apical region was afterwards illuminated laterally, formed the basis upon which all this superstructure of experiment and theory upon growth regulation in the plant has since been erected, so that it is entirely appropriate he should be the author of this volume, which is now translated and revised by American workers in this new field.

Prof. Boysen Jensen is able to show that the theory that substances may be released from the apical tissue of the coleoptile and transported in some way to the elongating base of this structure, where they control the rate of elongation of the basal region, has rallied to its support a host of new experimenters with new methods; that analogous substances have been synthesized or extracted from such unlikely substances as urine; and that these substances are now suggested as essential parts of a general growth mechanism in the plant, regulating shoot growth and root growth, phototropic and geotropic response and, still more recently, suggested as controlling cambial activity.

The book covers very thoroughly, though necessarily very briefly, the whole of this wide field, and is most valuable, therefore, as presenting a clear, authentic picture of the range of experimental investigation in this new field. The first chapter contains a most ingenious double-page illustrated chart of the development of the new field of work, though this sketch, naturally brief,

links Loeb with views from which he departed very widely in his later writings on regeneration.

Such a book as this naturally evokes an appraisal, in the mind of the reader, of the general effect of this new phase of activity upon our knowledge of the plant. The present reviewer in earlier years ventured into print as a sceptic of the new hypothesis: he has had to consider again in the light of this book whether he finds this view of the mechanism regulating plant growth convincingly established.

The strength of the case has always been the experimental demonstration, first given by Boysen Jensen, that the severed tip of the coleoptile, laterally illuminated, in some way so modifies the growth of the coleoptile base beneath, with which no living tissue connexion is left, that a phototropic curvature occurs in this basal region. Since that time a host of experimenters, associated particularly with the Utrecht school, have devised most ingenious experimental technique showing that substances which diffuse from the base of the excised coleoptile tips, and which may be collected on agar disks or in other ways, can modify the growth-rate of the coleoptile. Much has now been learnt of the growth of the coleoptile; throughout the period of phototropic response the growth is almost entirely by cell extension, not cell multiplication, so that a tendency has been to term this growth-modifying substance an auxine rather than a hormone, and much valuable work has been done on an analysis of the factors controlling cell extension; but it may be gathered from this review that as yet no definite conclusion can be drawn as to the way in which auxine or hormone affects this mechanism of cell extension.

The channels and mechanism of transport of the hormone from apex to base still remain mysterious, but in view of the state of our knowledge of water or food movement in the plant this is perhaps not surprising; the reviewer is still intrigued by the hypothesis that the growth regulator is secreted mainly by the apex of the coleoptile. There is a curious contradiction here that runs throughout this field of work. Investigators of the coleoptile have learnt to regard the growth-regulating mechanism as regulating cell extension, but their experimental results are freely quoted by investigators who are claiming growth-regulating effects on the meristematic tissues of buds or of cambia. Similarly, many investigators now report, in other plants, a distribution of the growth hormone which is correlated with the

meristematic activity of the plant tissue, and yet this apex of the coleoptile, like most other monocotyledon leaf apices, is a region that has ceased to grow.

In this book Prof. Boysen Jensen repeats the curious argument that as a decapitated coleoptile begins to grow after a few hours, this must mean that there has then been a physiological regeneration of the tip from which growth hormones are again resuming their flow. The first experimenters to postulate this regeneration do not seem to have troubled to look to see if it occurred, and apparently the experimenter in this field is not interested in the fact that there is no visible regeneration. Fatty deposits accumulate over the cut stump, which ceases to bleed; no new cells are formed and no striking accumulation of protoplasm is visible in the cells below the injury. But it is not clear why regeneration is necessary; cells of the original apex were inert to all appearance, the cells below the cut surface are similarly so. It is one of the curious anomalies of this coleoptile story that the cells which are supposed to be most vigorously active in hormone production are conspicuously inactive in every other way, whilst the cells which will show most elongation during growth are situated in the part of the coleoptile farthest removed from them. The difficulty has been discussed by Went and others, and leads to further hypotheses, but the strength of the position of the author, and of the numerous botanists who think with him, lies in the fact that there is no alternative hypothesis which

adequately explains basal curvature in the hypocotyl when laterally illuminated only at the tip especially when that tip has been excised and replaced.

There may yet, however, be found some other explanation of this mechanism of stimulus reception and growth response, and at least until this mechanism is more fully understood some caution seems advisable in extending the hypothesis to cover growth mechanisms in general in view of the fatal facility with which a hypothesis can be constructed to explain anything, by postulating substances from unknown sources moving by unknown channels to work by unknown methods. The same mechanisms may apply in other growing systems as in the coleoptile—though meristematic tissues in dicotyledons may be expected to differ widely in behaviour from the vacuolating tissues of a monocotyledon leaf—but as yet we seem far from the stage when a satisfactory picture of growth regulation can be based upon our conceptions of such growth-regulating substances.

None the less, very interesting facts have emerged as to the action of some substances, in some cases chemically pure substances, in promoting callus formation on wound surfaces or in accelerating root production; and the rapidly growing army of workers in the new field, indicated by the extensive bibliography, is an ample guarantee that the possibilities of this new method of interpreting growth phenomena in the plant will be fully explored. J. H. PRIESTLEY.

Metallurgy of Gold

The Metallurgy of Gold

By Sir Thomas Kirke Rose and W. A. C. Newman. (Griffin's Scientific Text-Books.) Seventh edition, revised throughout and re-set. Pp. xiii+561. (London: Charles Griffin and Co., Ltd., 1937.) 36s. net.

DURING most of the period covered by known history, gold has occupied a special position in the thoughts and affairs of men. It has been responsible for explorations, migrations, wars and conquests, and it was in efforts to obtain it by transmutation that the science of chemistry had its origin. Recent developments in civilization have been such as to require the use of increasing quantities of iron and steel, copper, aluminium and certain other metals, which have become increasingly important through their numerous applications at the same time as gold has tended to disappear into deposit vaults. Nevertheless, the

position of gold is still unique, and the quest for it is scarcely less eager than in the past.

Other metals become more important as the number of useful purposes for which they can be employed increases. Gold, however, is scarcely affected by such factors, and although its present use is symbolic rather than tangible, it is being produced in larger quantities and sold at a higher price than at any previous time. Gold, in effect, is an economic instrument, and, unlike other metals, it passes out of the sphere of industry into that of economics and finance after it has been extracted from its ores and refined. This affects the metallurgy of gold, in that little attention is given to such aspects as alloying, fabrication, treatment and behaviour under different conditions of service, which are of great importance in the metallurgy of other well-known metals. Thus, in the book under review, most of the space is

voted, as it should be, to the plant and technique and the phenomena involved in obtaining gold from its ores.

The book begins with an account of the physical and chemical properties of gold. This is followed by a description of the binary alloy systems formed by gold and a number of other metals. Many such systems have been studied, and some of them exhibit features of considerable scientific interest; but the only metals alloyed with gold for practical purposes are copper, silver, palladium, nickel and zinc. In the third chapter, the chemistry of the compounds of gold is considered, and the remainder of the book consists of fourteen chapters on the processes of crushing, grinding, concentrating, extracting and refining used in the metallurgy of gold, and three on assaying and ore testing.

In one sense, this book may be regarded as the seventh edition of a classic work the first edition of which appeared in 1894 and the sixth in 1915. In another sense, however, it is a new book, for the name of W. A. C. Newman appears for the

first time on the title-page along with that of the original author, Sir Thomas Kirke Rose. The combination has proved very effective, for whereas the general plan of the book and much of the original matter have been retained, new chapters on flotation and ore testing have been added and the original chapter on chlorination omitted, while throughout the text as a whole new information has been included and obsolete matter deleted so as to present a balanced account of the subject as it is to-day. All this is very important, for standard works of this kind are, or should be, primarily intended for those who desire to learn something about the subject, and are not prepared to provide interesting reading for those who are sufficiently well informed to sort out the up-to-date information from that which applies to the past. Actually the present work is more up to date than most new editions of classic works produced after a lapse of time, and better arranged than a new book appearing for the first time.

J. M. R.

Geology in Engineering

Engineering Geology

by Prof. H. Ries and Dr. Thomas L. Watson. Fifth edition. Pp. vii+750. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 25s. net.

THE fifth edition of this well-known work is to be especially welcomed in Great Britain, where geologists pay far less attention to the allied sciences than is the case abroad, with the result that we have not yet produced a book dealing with the application of geology to civil engineering problems—a position to be regretted.

The number of rock-forming minerals dealt with in Chapter i is rightly reduced to the bare minimum required by engineers, some two hundred pages on rocks and their structural features following. Rock-weathering and soils, treated in Chapter iv are probably of less importance to engineers than is realized by the authors, while the treatment of run-off is disappointing, since this offers a ready, and so far untapped, field for the application of precise geological methods. It is, however, a relief to find a book which does not give Stokes's law for the elutriation of sediments. The section dealing with sub-surface waters is extremely interesting, and goes to show that a great deal more work has been done on this branch of the subject in the United States of America than in Great Britain.

Landslides are discussed adequately in Chapter vii, the matter on wave action being less closely linked with civil engineering practice. Lakes and glaciers are quite briefly treated. The geology of reservoir and dam sites is well covered in Chapter xi; but some of the recent work on building stones, both here and abroad, is not mentioned in the following chapter, which is otherwise ample enough.

The technology of limes, cements and plasters is so varied that one is not surprised to find it described briefly in eighteen pages, and this is also true of the clays and clay products treated in fourteen pages. It is obvious that a book which goes on to deal with coal, petroleum and natural gas, ore deposits and the outlines of historical geology, requires considerable ingenuity on the part of the authors as to what to include and what to omit, so that the allocation of only fourteen pages to road materials, a subject the importance of which has greatly increased in recent years, is quite understandable. In a later edition, perhaps, the application of recently developed microscopic methods might be added to this portion with advantage.

This work can be recommended to the student of civil engineering and to the practising engineer as being certainly one of the best, if not the only one, of its kind.

B. H. KNIGHT.

The Mechanism of Nature

being a Simple Approach to Modern Views on the Structure of Matter and Radiation. By Prof. E. N. da C. Andrade. Revised and enlarged edition. Pp. xii+188+8 plates. (London: G. Bell and Sons, Ltd., 1936.) 6s. net.

THIS book is chiefly intended for the man who has not had the advantage of a scientific education but is anxious to know something of modern scientific developments. There are no mathematical formulæ to put the reader off. Sir James Jeans says somewhere that without considerable mathematical knowledge it would be quite impossible for anyone to understand those branches of science which deal with the fundamental nature of the universe, as, for example, the theory of relativity, the theory of quanta and wave mechanics. So the reader must not expect to be able to do this unless he be a well-equipped mathematician. Prof. Andrade, however, is so skilful in the use of words that his statements impart all there is to know on these subjects short of the employment of mathematics.

In this, the fifth edition, the whole book has been revised and alterations and additions have been introduced to bring it into harmony with recent work. The treatment of cosmic rays has been modified to accord with advances made since the last edition, and a brief account is given of the recent discovery and meaning of heavy hydrogen, the neutron and the positron, of artificial radioactivity and the striking development of artificial transmutation of matter. The explanation of the cause of isotopes—substances which have the same chemical properties but different atomic weights—is of much interest; 'heavy hydrogen' is the most remarkable of these. Another matter of interest is the question of how artificial atomic transmutation was brought about, to which Lord Rutherford has contributed so much. It has, however, so far never produced weighable quantities of any new atom, but established the possibility of transmutation. This, of course, completely revolutionizes the classic ideas of the nature of the atom. All these are treated with admirable clearness by the author, who is a master of exposition where complicated matters are concerned.

H. L. C.

Aftermath:

a Supplement to the Golden Bough. By Sir James George Frazer. Pp. xx+494. (London: Macmillan and Co., Ltd., 1936.) 21s. net.

It might seem that the twelve volumes of "The Golden Bough" had already covered the ground more than adequately, and stood in no need of a supplement. Here, however, the author has gathered together data, not numerous, which had escaped his attention previously, and the more important items of evidence bearing upon his arguments, which have accrued in field work since the publication of the last edition of the major work. Hence this new volume is a corpus of additional facts, corresponding in its division into chapters with the arrangement of topics in "The Golden Bough", but making no addition to theory, except by way of corroboration.

Much of the material will already be familiar to anthropologists, who have not failed to note on numerous occasions how investigations in the fields of inquiry have served to confirm interpretations first tentatively suggested in "The Golden Bough". Prof. Seligman's Frazer Lecture dealing with the magical ritual of kingship, of which his own investigations among the peoples of the Upper Nile formed the starting-point, affords perhaps the most striking instance of the prescience shown by Sir James, not once alone, but on many occasions. Notwithstanding advancing years, the hand of Sir James has not lost its cunning. His latest work in no way falls behind its many predecessors in style and charm of diction.

Marconi:

the Man and his Wireless. By Orrin E. Dunlap, Jr. Pp. xxii+360+16 plates. (New York: The Macmillan Co., 1937.) 16s. net.

THE author gives a good and temperate account of the life-work of one of the world's greatest inventors. One of the early pioneers of radio attributed Marconi's success chiefly to his instinctive intuition as to what was wanted and the best way of getting the solution. It must not be forgotten that he had a companion with plenty of capital behind him and that his success or failure depended upon the rapid development of radio in the early days. With this money behind him he had the courage to launch out on great experiments. The fact also that the organization was called the Marconi Company added greatly to his prestige and always kept his name prominently before the world. When 'Cables obtained control of Wireless' in England, and the Marconi Company became practically a manufacturing organization, the most interesting period of its life has passed.

The author describes both the 'man' and the 'inventor', and links them together into one personality. Marconi crossed the Atlantic eighty-nine times on voyages of scientific research and good will. This view of him from an American angle throws much light on his career. We hope that it will not become customary in the United States to refer to Oliver Heaviside as Sir Oliver Heaviside.

Hardness of Metals

By Dr. F. C. Lea. Pp. vii+141. (London: Charles Griffin and Co., Ltd., 1936.) 12s. 6d. net.

THE hardness of metals, as Dr. Hugh O'Neill once said, like the storminess of seas, is easily appreciated but not readily measured. Prof. Lea has attempted to describe the various methods of measuring hardness, to establish, from the results of a long series of tests, the relationships between hardness measured by each of these methods, and thence, by means of curves and a chart, to make it possible within certain limits of accuracy to obtain corresponding hardness numbers as determined by the various methods. The book is not so much a discussion of 'the hardness of metals', therefore, as a collection of hardness data obtained on a series of materials comprising chiefly heat-treated steels.

Boucher de Perthes and the Foundations of Prehistoric Archaeology

PREHISTORIC archaeology, being one of the younger among the sciences, has had few opportunities of celebrating centenaries. It is a little more than a hundred years ago that the excavation of Kent's Cavern, Torquay (1825-29), first afforded a warrant for the tentative suggestion that man had lived in some remote past as a contemporary of an extinct mammalian fauna. Until this coexistence was demonstrated conclusively, discussion of the antiquity of man had no solid factual basis of inference on which to proceed. For this reason, Boucher de Perthes, on account of his discoveries of flint implements in the valley of the Somme, derived from geological strata in which they were shown to be associated with the fossilized remains of extinct mammals, has been regarded as the founder of prehistory, and more especially of that branch of archaeological studies which deals with the industries and cultures of the Old Stone Age.

It was in August 1837, according to his own record made not long afterwards, that Boucher de Perthes initiated his investigations of the geological deposits of the Somme valley for evidence of early man, and acquired the first objects in his collection. There is reason for thinking, however, that the correct date may have been in the following year. In fact, if Boucher de Perthes's statements be accepted, it is difficult to follow the course of events, or arrive at a just estimate of the credit to be assigned to him in the crucial discoveries in the later 'thirties and the 'forties of the last century.

In 1837, Boucher de Perthes was neither archaeologist nor geologist. On his return to Abbeville from Paris in 1830, he was known only as an unsuccessful writer of satirical drama and tendentious political economist, who had been expelled from the public service on account of his radical views; while up to 1841 he was immersed in the publication of a vast work entitled "La Création" on metaphysics, a subject in which, on his own showing, he had never read a word, and in which he relied not so much on his reason as his imagination. Writing in 1863, he claimed that so far back as 1805, when as a youth of seventeen he visited the Cave of Roland at Varsailles, and again in the Papal States in 1810, he idea of discovering evidence of man as a contemporary of extinct mammals had been before him. But in making this claim, as well as others for an early dating of his views on the antiquity of man, his recollection was coloured by after

events. These dates cannot be substantiated. His memory was highly imaginative, and he verified neither his recollections nor his dates.

Recent research in the early records of archaeological studies in France has shown that prehistory, unlike Minerva, did not spring full-fledged from a single head. In Great Britain, the discovery of flint implements at Hoxne by John Frere in 1797 gave a lead; similarly, in France from the early years of the nineteenth century, archaeological discovery, as for example in the work of Jouannet in Périgieux, was pointing the way to the recognition of primitive phases in the development of civilization transcending by far the time limits then fixed by archaeologist, palaeontologist and geologist alike, whose vision for the time being was bounded by the views of Cuvier on the recent origin of man.

The apparent paradox of Boucher de Perthes's achievement as the founder of prehistory by his discoveries in the valley of the Somme, when contrasted with his character, attainments and previous history, has led M. Aufrère of the Institut de Géographie in the University of Paris* to examine not only his published works and correspondence, but also the drafts of his writings and letters with their numerous deletions, alterations and amendments, as well as the records of scientific activity at Abbeville at that period among those with whom Boucher de Perthes and his father before him were in touch. The result has been to throw an entirely new light on the course of events, and to give a new orientation in the investigations made by Boucher de Perthes, while meting out justice to the inspiration to which they were due.

The story begins with the foundation of the Société d'Emulation at Abbeville in 1795. Of the original members the most distinguished was Emmanuel Baillon, who had been of signal assistance to Buffon in his great work on natural history by his accurate observation of birds. Five years later, Cuvier was elected a member, and the announcement of his election was accompanied by a box of fossil bones of mammals found by the members in the neighbourhood of Abbeville. Cuvier's influence on the ideas and pursuits of the members of the society was considerable, especially in the domain of geology and palaeontology. His view of the recent origin of man largely determined their attitude in discussing archaeological material.

* *Le Mouvement Scientifique à Abbeville dans la Première Moitié du XIX^e Siècle et les Origines de la Préhistoire (1795-1840)*. Par L. Aufrère. *Sciences, Assoc. Fr. pour l'Avant. des Sciences*. No. 4, 1936; *Banquet sur les Premières Découvertes de Boucher de Perthes et les Origines de l'Archéologie Primitives (1838-1844)*. Par L. Aufrère. *Épreuves et Synthèses*, No. 1. (Paris. L. Staude, 1936.) Also other papers.

This accounts for the readiness of Boucher de Perthes and others to maintain, or, on occasion, revert to, the view that the stone implements discovered in the Somme deposits, like those found elsewhere, were 'Celtic'.

In the work of the fifty years which followed the foundation of the society, closing in 1844-45 with the presentation of the account by Boucher de Perthes of his discoveries, the achievement of certain of the members stands out. Of some of these only a brief mention must suffice.

The first in chronological order is Laurent Traullé (1758-1828), palaeontologist and archaeologist, wild in theory, but excellent in observation and discovery. It was he who supplied Cuvier with the fossil remains of elephant, rhinoceros, Bovidae, horse and deer. He was the finder, in 1814, of a 'Celtic' hafted axe; but his most noteworthy contribution to archaeology was the recorded observation of the stratified cultural sequence in the deposits of 'Celtic', Roman and 'Francisque' in this invariable order—an observation pregnant for archaeology, albeit unfortunately forgotten until revived more than twenty years later. Most important of all, however, was his account of the stratification of the geological deposits of the Somme valley, the first of its kind.

Of those who were working at Abbeville in the years preceding Boucher de Perthes's investigations, two names to be noted are those of Alfred Tillet de Mautort and Dr. F. P. Ravin (1795-1849); both careful observers of geological evidence, whose detailed accounts of stratification in recording archaeological finds brought archaeology and geology into intimate relation. Dr. Ravin's authoritative records of geological formations were later to prove of much value to Boucher de Perthes, who made use of his specialized knowledge to support and authenticate his own observations.

The full implication of the relation between geology and archaeology in the work of Ravin and de Mautort was developed by Casimir Picard, a name that has been forgotten, but deserving a better fate as that of an outstanding personality in the scientific, and more especially the archaeological, activities of the Abbevillians between 1830 and 1840. Picard was born at Amiens in 1806, and went to Abbeville from Paris as a qualified medical man in 1828. Widely interested in scientific pursuits, but especially botany, palaeontology and geology, he had unbounded energy, and on attaining office in the Société d'Emulation rapidly spurred that body to strenuous activity. He was associated with Boucher de Perthes in the organization of the Abbeville Museum, an association which, as M. Aufrère suggests, may have been responsible for the

foundation of prehistory. His powers of lucid and cogent archaeological argument were far in advance of his time, and would stand the test of modern application. In fact, his contributions to archaeological theory went far to lay the foundation of archaeology as a science. Of these, the most important were the rehabilitation of the flint implement as something more than an unfinished stage, or a reject in the manufacture of a polished implement, as was then held; the demonstration of the relation of core, or nucleus, and flake as correlatives in the technique of flint fracture; and the argument from stratification for the contemporaneous character of deposits and contained artefacts, and hence the inferred coexistence of man and extinct fauna as contemporaries.

In May 1838, Picard presented a preliminary sketch of a report on the antiquities of Abbeville to be prepared in response to an official request. From this it appears probable that he had in mind a project for a series of excavations and investigations in the neighbourhood of Abbeville. Unfortunately, pressure of other interests, such as the foundation of the Linnean Society in Northern France in 1838, drew him away; and three years later, in March 1841, he died at the early age of thirty-four years. Had his life been prolonged, there can be no doubt that the early history of prehistoric discovery in the Somme valley would have been far different. His precision and appreciation of scientific method would have averted the ineptitudes which delayed the acceptance of Boucher de Perthes's very considerable contribution to the advancement of knowledge.

Picard's archaeological insight and his enthusiasm, however, were not to be without effect. On more than one occasion Boucher de Perthes recorded that his investigations, whether beginning in 1837 or in 1838, were first undertaken, with some reluctance and even distaste on his part, in order to continue the work which Picard had planned and no doubt hoped to carry out himself. His death took place before he realized that anything but a 'Celtic' antiquity was involved, and that his plan of campaign, if it produced any result at all, would lead to the discovery of diluvial man. Nor was Boucher de Perthes, in his early investigations at La Portelette, Menchecourt and the Hôpital site, in better case. So far from appreciating that his aim, as he afterward claimed, was fossil man, it was some time before the distinction, which appears on the title-page of his capital work, between "antiquités celtiques" and "antiquités antédiluviennes" was presented to his mind. Unfortunately, when the reported occurrence of pottery and stone implements, especially of axes, which first appeared in 1841

onvinced him, though he had not seen these finds *in situ*, that he was dealing with diluvial man, the heterogeneous character of the finds, which included Venetian glass, as well as knives and axes of stone which would now be termed eolithic, only provoked ridicule when submitted to expert examination. Boucher de Perthes then reverted to the idea that they belonged to a 'Celtic' civilization, though still maintaining their association with an extinct fauna. It was not until 1843 or 1844 that he saw, *in situ*, the first of the axes, now to be regarded as Lower Palaeolithic, which confirmed his contention of the existence of diluvial man. This find from the Hôpital site

heralded the evidence which, notwithstanding such vagaries as a large proportion of fractured flints of non-human origin, and a collection of so-called representations of animal forms, was to win a verdict in his favour from the British commission of inquiry of 1859.

So far as the foundation of prehistory was the outcome of anything like a scientific conception of the aims and methods of archaeology, the credit belongs to Picard rather than to Boucher de Perthes; but to the latter must be conceded a tenacity of purpose which carried through the actual investigation and won recognition in the end.

The Proposed Everglades National Park, U.S.A.

By Dr. John Kunkel Small, New York Botanical Garden

THE proposed Everglades National Park, recently authorized by the Congress of the United States, after thirty years agitation, is of importance to all who are interested in outdoor life. Its area (capable of enlargement) of two thousand square miles is less than that of several national parks in the United States and elsewhere; but it surpasses in the abundance, variety, and activity of plant and animal life. In most large parks life is in a decline. Variety is giving way to uniformity. Erosion is tearing down mountains; species are disappearing; plant and animal life is maintained with difficulty in increasingly artificial conditions. Such is not the case in the Everglades. Both at the outer fringes of mangroves and far within, land is naturally and continually increasing. Life in the warm humid climate is luxuriant, active—primeval, as if species were making. Plants and animals live as they have for ages, and as they may continue to live for years to come.

The area (Fig. 1) is not technically within the tropics, but the Tropic of Cancer lies only seventy-five miles distant, and ocean currents, prevailing winds, and migratory birds have found a strictly tropical rendezvous scarcely surpassed anywhere in congenial conditions and lack of disadvantages. The area is about equally divided between land and water. The highest points of land are scarcely ten feet above tide, and the water has an average depth of but a fathom or so. Most of the area is accessible by boat in protected waters, a mode of transportation least disturbing to wild life. However, when roads and trails are desirable they can be built at little expense.

ANIMAL LIFE

There are few places where marine life is so abundant and active; the greater part of it is in continuous motion and change, either anchored or free swimming. On one hand, this fact can be observed and studied in the shallow crystal-clear waters of the vast continental shelf on which the Florida Keys now stand and which fringe the mainland. These waters are teeming with life, in almost innumerable quantities and variety. A handful of mud from a bleak and lofty area like the United States Great Smoky Mountain Park will remain motionless; a handful from the Bay of Florida will be in continuous motion as a result of the included active marine life. The kinds of lowest animals—sponges, jellyfish, corals, sea-anemones, moss-animals, molluscs, sea-urchins, sea-cucumbers, starfish and stone lilies—are legion.

Associated with these, fish of almost innumerable kinds, forms, and colours, and great range in size, abound in the waters, fresh and salt. The vast numbers of fish may be realized by the fact that the schools are often so large that they fill bays and sounds to the exclusion of a great part of the water.

Ascending in the life-scale, we find amphibians and reptiles. Frogs abound. Several kinds of large turtles are found, and the alligator and the crocodile are outstanding. Among serpents is the dangerous cotton-mouth moccasin and the largest and most dangerous American reptile, the diamond-back rattlesnake, which sometimes attains a length of nine feet. Lizards are numerous, but most of them are small.

More evident than the amphibians and reptiles are the birds. The bird life of this region is prodigious, ranging from the minute humming-bird to

the wood ibis and the golden eagle. Naturally, from the make-up of the country, both land and water birds abound. The latter are often seen in greater abundance. As a result of their feeding habits—diurnal and nocturnal—flocks of innumerable birds, like flakes of snow in a storm, may be seen in flight both day and night. The sight of their going and coming between the feeding-grounds on a bright moonlight night, not to mention the uncanny noises of their cries and the swish of wings, is something never to be forgotten. Black and various colours of plumage are continually seen. Very conspicuous are the white and pink ibis and the rare roseate spoonbill, of which thousands, even hundreds of thousands, were

of eastern North America roam through the wilderness. Prominent among these are the panther, lynx, bear, deer. Curiously enough, the otter lives here just as it does in the Hudson Bay region. The larger aquatic mammals are the massive sea-cow and the whale.

PLANT LIFE

Broad-leaved vegetation is the most evident form of plant life to the casual observer, whether it be in swamp, prairie, or hammock; but underneath it grow ferns and flowering plants bewildering in attractiveness and variety. In this tropical wilderness, vegetation grows to its full stature and natural age without interference from man.

It is true the destructiveness of Nature is rampant; but it is normal and in its way orderly. Plants and animals grow rapidly and soon return to dust, a process hastened here by a moist warm climate and the presence of a host of fungi and bacteria ever ready to do their work. In spite of the natural inroads, as the source of supply is inexhaustible, the floor is maintained while the land gradually rises higher and higher above the tides.

In the Everglades, tropical vegetation dominates; but the ranges of north temperate tree dovetail with those of the West Indian tropics. The north temperate elements have extended southward through the hammock and along the cool waters of the prairies. The tropical ones have been brought beyond the tropic by the warm ocean currents, the winds, and the birds; and

thus plants of opposite temperature requirement mingle, and there is a unique balance in life-form.

Withal it is a strange country, a land of anomalies and the grotesque. Here fish sing*; snakes often live in trees; epiphytes grow as terrestrials; terrestrials grow as epiphytes; giant oak trees are harbours for aerial plants and ferns; cacti grow in water; oysters grow on trees that dip into the creeks; large pine trees and broad-leaved trees grow on rocks lacking soil; fig-trees grow as petriphytes trying to strangle the rocks; giant palms more than a hundred feet tall and cactus trees thirty feet tall grow as humus-plants; strangler figs kill other trees, and often turn upon themselves and commit suicide.

* On the reef small fish attach themselves to the hull of a boat after dark and give off their plaintive notes all night long.

Fig 1.
THE PROPOSED EVERGLADES NATIONAL PARK.

formerly seen at a time. The well-known egret is a decorative associate. The smaller highly coloured migratory birds pass this way, and are evident in season at this midway station.

On the land, one finds the insects universal as well as yet innumerable. The numbers of kinds can be only roughly estimated. Fascinating and grotesque forms may be seen everywhere. A short description of them would fill volumes. Many of the kinds are almost or quite microscopic; but large and ornate butterflies and moths abound. Less graceful but fascinating are the devil-horses, a showy grasshopper commonly six inches long which travels over the land by the million devouring vegetation as it goes.

Mammals are present on the land and also in the water. Several species of the large quadrupeds

Bioclimatic Zones of Australia*

By Dr. J. Davidson, Waite Research Institute, University of Adelaide

TEMPERATURE and moisture are the chief factors affecting the physical environment of terrestrial plants and animals. In association with soil type, they exert a dominating influence on geographic distribution and seasonal abundance. In Australia, moisture is the chief limiting factor; temperatures during winter are moderate, the mean for the coldest month being above 43° F., except in parts of Tasmania and the highlands of Victoria and New South Wales. The essential elements of climate, on which the availability of moisture depends, are precipitation and atmospheric humidity; loss of moisture by evaporation influences the effectiveness of precipitation.

During recent years, attempts have been made by various workers in climatology to develop a formula by means of which the efficiency of rainfall may be assessed in relation to the moisture requirements of plants and animals. These investigators have taken into account the influence of temperature and atmospheric humidity on the rate of evaporation from an exposed surface. The simplest formula is the ratio proposed by A. Meyer in 1926, in which precipitation is related to evaporation by dividing annual values for rainfall by appropriate values for atmospheric water vapour saturation deficit, both expressed in inches or centimetres. Annual values for these elements are inadequate for bioclimatic studies, particularly in Australia, owing to the seasonal character of the rainfall and its unreliability over the greater part of the continent.

It is recognized that the best index to the relationship between climate and moisture at the soil surface is the ratio of precipitation to evaporation, the critical value being $P/E = 1$; with decreasing values dryness increases, with increasing values wetness increases. Unfortunately, suitable records for evaporation are available at comparatively few stations.

Where adequate data for temperature, rainfall, atmospheric humidity and evaporation are available they can be used to interpret the moisture and temperature 'conditions' in the environment of plants and animals. From the point of view of ecology, zones in which the essential elements of climate can be assessed in this respect may be defined as 'bioclimatic zones'. The flora and

fauna of the different zones may be related to similar or different environments. This emphasizes the significance of environment, in contrast with the conception of phylogenetic grouping of animals, implied in the boundaries of the faunal regions of the world as defined by Alfred Russel Wallace. The term 'bioclimatic zone' was used by A. D. Hopkins (1921), who considered temperature to be the most trustworthy guide to the range of the zones. Experimental work since that time has abundantly demonstrated that temperature alone does not give a true index to the effect of climate on the flora and fauna of an area; the index must express the effect of moisture and temperature working in combination.

I employed the Meyer formula as a monthly ratio (P/S_d) in order to assess the degree of wetness or dryness over Australia, month by month. For this purpose, P/S_d was interpreted in terms of evaporation, (P/E) by reference to records for evaporation at the capital cities. Values for P/E were computed for 235 stations in the Commonwealth. The continent was divided into areas showing the areas and months in which values for P/E are greater or less than 0.5; the value 0.5 was selected tentatively as the minimum value, below which adequate moisture will not be available for general plant growth. The areas were grouped to form the five moisture zones defined in Fig. 1. For each of these zones it is known how many consecutive months have values for P/E greater than 0.5.

The intensity of dryness in any zone depends upon the number of consecutive months that values for P/E are less than 0.5, together with the value of the ratio. The intensity of wetness in any zone depends upon the number of consecutive months in which values for P/E are greater than 0.5, and the value of the ratio. In the central portion of Fig. 1, values for P/E are less than 0.5 for every month of the year; the region is classed as an ecological 'desert', the vegetation is characterized by acacia - semi-desert, shrub steppe and porcupine grass climax associations. The boundaries of this region, as shown in Fig. 1, differ somewhat from those obtained by employing the climatic relationships of desert areas as interpreted by Köppen (1923). The arid regions are defined as having one to six consecutive months in which P/E exceeds 0.5; they have been grouped to form the arid and semi-arid zones. The humid regions are defined as having seven to twelve consecutive

* This article gives the chief features of a series of four papers by the author dealing with certain aspects of bioclimatology (*Trans. Roy. Soc. S. Aust.* 1934-1936); under the same title, it formed the subject of a paper given at the Auckland (1936) meeting of the A.N.Z. Ass. Adv. Sci. (Section D, Zoology).

months in which P/E exceeds 0.5; they have been grouped to form the semi-humid and humid zones. It is of interest to note the small area of Australia, north of the Tropic of Capricorn, which falls in the humid zone.

The temperature zones have been defined on the following basis:

A. *Hot*—the mean annual temperature exceeds 70°F .

The boundaries of the various zones appear to give a better fit to the actual climate in the zone than those developed by Thornthwaite (1933) who assessed "precipitation effectiveness" by evaluating the P/E ratio from data for rainfall and temperature.

There is a close agreement between the bioclimatic zones shown in Fig. 1 and the distribution of types of native vegetation; also there is

Fig. 1.

B. *Warm Temperate*—the mean temperature for the coldest month does not fall below 43°F .

C. *Cool Temperate*—the mean monthly temperature may fall below 43°F . during one to five months of the year.

In local areas at high elevations in Zone C, the average monthly temperature may fall below 43°F . for more than five months; these areas may be classed as having a cold climate.

The methods described above give a good index to the climate in the different zones; improvement in detail will be obtained when allowance can be made for the influence of additional factors affecting evaporation, such as air movements.

correlation between these zones and the distribution of areas where particular agricultural crops are grown, and the sheep and cattle carrying capacity of the pastoral country. This has an important bearing on the question of settlement in Australia. The methods may be useful as means of obtaining an estimate of the potential population of the Commonwealth, on the basis of land utilization and production.

It is easier to assess the influence on plants than on animals, of the physical environment as determined by climate. This is particularly so with active vertebrates which can readily move away from adverse local conditions.

Obituary Notices

Prof. E. B. Elliott, F.R.S.

PROF. EDWIN BAILEY ELLIOTT, sometime Waynflete professor of pure mathematics in the University of Oxford, honorary fellow of the Queen's College, and formerly fellow of Magdalen College, died at Oxford on July 21 at the age of eighty-six years.

Prof. Elliott was the son of Mr. Edwin Litchfield Elliott, of Oxford, and was educated at Magdalen College School, from which he obtained a demyship to Magdalen College. He took his degree in 1878, after obtaining first classes in mathematics, both in Moderations and in the Final School, and in 1878 was awarded the senior university mathematical scholarship. In 1874 he was appointed fellow and mathematical tutor at the Queen's College, holding the office for nearly twenty years, until in 1892 he was elected to the Waynflete professorship of pure mathematics, and so returned to Magdalen as a fellow. He resigned the professorship in 1922. He joined the London Mathematical Society in 1875, and was for a long time an active member, serving in the Council for many years beginning from 1882; he was president of the Society in 1896-98, being preceded in the chair by Major MacMahon and followed by Lord Kelvin.

All his life, Prof. Elliott produced a steady flow of papers giving the results of his investigation and research. They are to be found in the *Proceedings of the London Mathematical Society*, the *Quarterly Journal of Pure and Applied Mathematics*, and the *Messenger of Mathematics*. His chief work was done in the algebra of invariants, but he also published important papers on Frullani's integrals, on other definite integrals, and on differential invariants.

When Sylvester went to Oxford as Savilian professor of geometry, in succession to H. J. S. Smith, he was full of his theory of reciprocants and of the transformation of differential operators, a theory very much akin to Sophus Lie's theory of continuous groups. Under the influence of Sylvester's enthusiasm, Elliott wrote a paper "On the Interchange of the Variables in certain Linear Differential Operators" (*Phil. Trans. Roy. Soc.*, 1889). He was elected a fellow of the Royal Society in 1891.

His great work, "An Introduction to the Algebra of Quantics" (first published in 1895, second edition, 1913), made Elliott's name well known to all English mathematicians, and thirty years ago was a textbook for all students of higher algebra. He says in the preface, "The primary object of the book is that of explaining, with all the clearness at my command, the leading principles of invariant algebra. . . . Lucidity in mathematical works has often suffered from undue compression. My constant aim has been to guard against such a possibility here. . . . The title Algebra of Quantics is perhaps one of my own introduction. It probably needs no defence, and can

scarcely fail to convey the right meaning. The mathematical world has now for half a century associated the algebra of invariants and co-variants with the name of Cayley and with his 'Memoirs on Quantics' so that it may perhaps be regarded as appropriate that a new work appearing in a year which has seen the close of the labours of the renowned author of these memoirs, and dealing with their subject, should bear a name which recalls his memory".

It is interesting to note that in the "New English Dictionary" there are three quotations under the word "Quantic", the first being from Cayley (1854) whilst the last stands thus "1896. E. B. Elliott. (title) An Introduction to the Algebra of Quantics". The book is a masterly exposition of results due to Cayley and Sylvester, and of those due to Salmon, MacMahon and Elliott himself.

Elliott's last published paper (*J. Lond. Math. Soc.*, 1; 1926), which bore the title "A Simple Exposition of some Recently Proved Facts as to Convergence", was a proof of Hardy's theorem that if b_n denote the arithmetical mean of the positive numbers, $a_1, a_2, a_3, \dots, a_n$, and $k > 1$, then

$$\sum_1^n b_r^k < \frac{k}{k-1} \sum_1^n b_r^{k-1} a_r < \left(\frac{k}{k-1}\right)^k \sum_1^n a_r^k.$$

This was an inequality of great interest to all workers in the theory of convergence, and Elliott's proof was greeted with enthusiasm by Hardy as the best, and in fact the last, word on the subject.

All who have studied mathematics at Oxford in the last forty years will feel that they have lost a friend now that Elliott is gone. He was always ready to help and encourage his younger colleagues with criticism and advice, and mathematics at Oxford owes him a great debt. A. L. DIXON.

Prof. P. Gardner

PROF. PERCY GARDNER was born on November 24, 1846, and passed away on July 19 last, after a few days illness, interested almost to the last in ideas, persons and things, and above all, in his friends. He was educated at the City of London School, and after a year's experience of business went to Christ's College, Cambridge, where he graduated with first-class honours in the Classical and in the Moral Sciences Tripos, and was elected a fellow in 1872. He had already entered the British Museum, and under great chiefs, Lane Poole and Barclay Head, spent fifteen years in a remarkable combination of metrological and æsthetic studies which determined his outlook on antiquity, while it earned him European repute. In 1877 he visited Greece, at a stirring time; Mycenae and Olympia had been excavated; there was talk of work at Pergamon, and even around the Acropolis of Athens. In 1880

he was appointed Disney professor of archaeology at Cambridge, concurrently with his museum work; and it was with this double experience that he entered on his professorship of classical art and archaeology at Oxford in 1887. Since 1880, too, he had been one of the original editors of the *Journal of Hellenic Studies*, and responsible for the high standard of scholarship and wide scope at which it aimed.

Classical archaeology was in its infancy in 1887 as an academic subject in Oxford. Gardner's only predecessor, Sir William M. Ramsay, had been interested in exploration and in epigraphy, and had spent much of his time in travel. There were valuable collections, the 'Arundel Marbles' and the like from seventeenth century patrons of learning; and the new Keeper of the Ashmolean Museum, Sir Arthur Evans, was accumulating new materials in classical as well as prehistoric archaeology. But there were few books, no casts or place for housing them; for a disastrous bargain had glutted the University Galleries with replicas of the works of Sir Francis Chantrey. But even before the reorganization of the Ashmolean Museum, and as part of a comprehensive plan, originals were installed, casts were acquired, and a modest work-shed was provided. Gardner's own conviction, bred of museum experience, and illustrated by his monumental "Numismatic Commentary on Pausanias" (1887), that in ancient coins we have a compendious and inexhaustible series of miniature illustrations of all aspects of Greek art, as well as of religious belief and local tradition, gave him initial advantage in planning his academic programme under such conditions, and in dealing with such early pupils as Sir George Hill and Dr. J. G. Milne. The breadth of Gardner's interests at this time is illustrated by his share in a collaborated "Manual of Greek Antiquities" (1892); his judgment and critical taste by his "Catalogue of the Ashmolean Vases" (1895) and "Sculptured Tombs of Hellas" (1896), and his deep philosophic interest in æsthetic problems by his "Grammar of Greek Art" (1905). As pupils became more numerous, systematic publication was less frequent, especially since there was no departmental staff, and only occasional lectures by college tutors supplemented the professor's own teaching. For many years, Gardner did the work of a college tutor for all his men, as well as his own. But he was a frequent contributor to the *Numismatic Chronicle* and the *Journal of Hellenic Studies*, and remained an editor of the latter until 1926.

It was during this later period too, from the publication of "Exploratio Evangelica" in 1899, that he allowed himself to give expression to his profound interest in the critical and historical aspects of early Christianity, in regard to which he combined what were then advanced liberal views with a simple reverence and personal piety which commended his scholarship and philosophical outlook to a wider circle of readers. From 1915 until 1923 he was president of the Modern Churchmen's Union, and remained an intimate and trusted counsellor of theologians of many schools. Though he took little public part in university business, he was a convinced advocate of research as an essential of university training,

and of facilities for it after graduation; and his "Oxford at the Cross Roads" (1903) expressed frankly and strongly what only a few of his colleagues had then begun to envisage clearly, still less to advocate or practise.

In 1925 Gardner retired as emeritus professor, but continued for some years to publish, and even, on occasion, to lecture; combining in his "Principles of Christian Art" his two dominant interests. In 1934 a slender volume of "Autobiographica" unveiled much that only intimate friends appreciated or suspected, of his devotion to scientific truth, to the interpretation of beauty in men's handiwork, and to the realization of his own high standard of living.

J. L. M.

Dr. A. H. Church, F.R.S.

DR. EDITH PHILIP SMITH, of the Department of Botany, University College, Dundee, writes as follows:

As an old student of A. H. Church, I should like to add a few words of appreciation and recollection to the obituary notice appearing in *NATURE* of May 22.

No one who has not had the privilege of studying under Church can fully appreciate the manner of man he was. To his students he was an unfailing (but not an uncritical) friend. No slipshod or incomplete work was tolerated: everything had to be done to a finish, in which he set an example by his unremitting application to his own research. But it was his dispassionate accuracy and integrity of purpose which created the deepest impression.

Church was an inspired teacher. The condensed and often cryptic English of his writings (which has prevented their full appreciation) became clear and enthralling when expanded in lecture or tutorial.

Church's writings have not yet taken the place they deserve in botanical literature, partly on account of their difficult style, and partly because they were all in advance of their time. The "Types of Floral Mechanism", for example, contains the prolegomena to a serious theory of the flower, which has scarcely been assimilated after twenty-nine years. I was told by Church that he had the remaining material of his projected study of the flower completed, but that the expense of publication was prohibitive. I do not know whether any project is on foot for a memorial to Church at Oxford, but I can think of no more appropriate tribute to his memory than to assist in the publication of his floral studies (if they still exist).

We regret to announce the following deaths:

Sir Edward Davson, Bart., K.C.M.G., an authority on Colonial trade and Imperial economics and a trustee of the Imperial Institute, on August 7, aged sixty-two years.

Sir David Masson, K.B.E., F.R.S., emeritus professor of chemistry in the University of Melbourne, aged seventy-nine years.

Prof. F. C. S. Schiller, emeritus professor of philosophy in the University of California, on August 6, aged seventy-three years.

News and Views

Bicentenary of Dr. Charles Hutton, F.R.S.

On August 14 occurs the bicentenary of the birth of the well-known English mathematician Dr. Charles Hutton, who for thirty-four years held the chair of mathematics at the Royal Military Academy, Woolwich, and who for a long period was a prominent member of the Royal Society. Born in Newcastle-upon-Tyne, Hutton was the son of a colliery labourer and though he attended a dame's school in the Gallowgate, he was almost entirely self-taught. He began life as an assistant teacher at Jesmond, and from 1760 until 1773 he conducted a school of his own in Newcastle and while doing so contributed to the *Ladies' Diary* and other periodicals, and published some excellent elementary works on arithmetic, book-keeping and mensuration. The failure of a bridge in his native city led him to write his "Principles of Bridges and the Mathematical Demonstration of the Laws of Arches", and in 1773 after a severe competitive trial he was appointed to the professorship at Woolwich, where he worked until 1807. In 1774, he was admitted to the fellowship of the Royal Society; in 1775 he made the calculations in connexion with Maskelyne's experiments at Schiehallion, Perthshire, for determining the mean density of the earth, and in 1779 was made LL.D. of the University of Edinburgh and foreign secretary of the Royal Society. This position he held until 1783, when complaints having been made of the way he had carried out his duties, he resigned. Sir Joseph Banks was then president, and Hutton's resignation raised a storm of protest at the way he had been treated. At a meeting of the Society on December 18, 1783, however, when Hutton submitted his "Defence", a resolution was passed stating "that if Dr. Hutton hath been in the opinion of any Member of the Society incriminated, it is the opinion of the Society that he hath fully justified himself".

Hutton already in 1778 had been awarded the Copley Medal for his paper on "The Force of Fine Gunpowder, and the Initial Velocity of Cannon Balls", and for many years he continued to add to mathematical literature. In 1785 he published his "Mathematical Tables" and this was followed by his "Tracts on Mathematical and Philosophical Subjects", his "Compendious Measurer" and his "Elements of Conic Sections". In 1795 he published his "Mathematical and Philosophical Dictionary" which was described by the "Encyclopaedia Britannica" as the most valuable contribution to scientific biography that had yet appeared in England. In 1803, with the naturalist Dr. George Shaw (1757-1813), and the physician and chemist Dr. George Pearson (1751-1828), he began the abridgement of the *Philosophical Transactions*, an arduous task which occupied him for six years and for which he received £8,000. Retiring from his post at Woolwich in 1807 on a pension of £500 per annum, he took up his residence

in Bedford Row, London. Recognized as a most skilful teacher and a man of amiable character, he died on January 27, 1823, in his eighty-sixth year and was buried in the family vault at Charlton, Kent. His "Life" was written by his successor at Woolwich, Dr. Olinthus Gregory.

Digestive Troubles among Omnibus Workers

THE belief that gastric disorders are unduly common among busmen is widespread among the men themselves and their leaders. The problem was placed before the Industrial Health Research Board, and considered by a joint Committee of the London Passenger Transport Board and the Trade Union of Transport and General Workers, and it was the unanimous opinion that an answer should be sought to the following question: Do omnibus workers suffer from digestive complaints more frequently or more severely (or both) than other groups of workers of similar economic and social position? The Committee of the Industrial Health Research Board considered that the investigation of the problem had in the first place to be statistical, and it was decided to make a comparison of the incidence of sickness (limited to periods of more than two weeks' duration) among omnibus workers and tramway workers. The investigation was undertaken by Dr. Bradford Hill, and the results of his inquiry are now published (Report No. 79. Medical Research Council Industrial Health Research Board. H.M. Stationery Office. Price 6d. net). An examination was made of the sickness records of omnibus and tramway workers in the employ of the London Passenger Transport Board. The data were extracted for the years 1925-26 and 1933-35, but the records of the first period were found to be unsatisfactory and the analysis of the sickness experience was therefore confined to the data relating to the years 1933-35. The age distributions of the omnibus and tramway workers differ considerably, and it was necessary to compare the occupational groups age by age, and in reaching a comparative figure for all ages to allow for the differences in the age distributions.

It is found that the omnibus drivers at all ages had in 1933-35 a relative excess of gastric sickness (that is, in proportion to sickness from all causes) of 12-14 per cent over the figure shown by the tramway drivers. In the same way, it is found that the omnibus conductors at all ages had a relative excess of gastric sickness of 15-18 per cent over the figure shown by tramway conductors. But this relative excess varies very considerably with age, for omnibus drivers being confined to the age-group 30-49, and for omnibus conductors to the age-group 20-39, and the higher figures at these ages must be balanced by the lower figures at other ages. When this correction has been made, taking only sicknesses of more than two weeks' duration and a wide group of diseases as

attributable to gastric causes, it is found that there was in 1933-35 some excess of gastric illnesses recorded among omnibus workers as compared with tramway workers at those age-groups to which the majority of the former belongs, though at these ages the total sickness experience, from all causes, of the omnibus workers was rather more favourable than that of the tramway workers.

Japanese Trawlers in Indian Waters

A LEADING article in *Current Science* of May directs attention to the rapidly increasing activity of Japanese trawlers in the Bay of Bengal. On more than one occasion the Government of India has been warned that unless adequate steps were taken to improve and develop Indian fisheries in Indian waters, some other country would sooner or later step in and exploit this area for its own benefit; but with the exceptions of the Government of Madras and, more recently, of Bombay, little or nothing has been done by either the Central or Provincial Governments. For some years past the average catches made by Japanese trawlers operating in the Pacific have been steadily decreasing, partly owing to increased competition but also in the main, no doubt, owing to over-fishing, and in consequence they are now seeking for more profitable areas in other waters. So long ago as 1908-9, the *Golden Crown* carried out a series of experimental trawls for the Government of Bengal, and these showed that there were a number of excellent trawling grounds in this area. The average catch obtained compared very favourably with those taken in European waters. The experiment was a failure from the financial side mainly because of difficulties in the distribution and marketing of the catches.

Indian Coastal Fisheries and their Exploitation

If the Japanese now working in the Bay of Bengal can overcome the marketing difficulties, there seems to be no doubt that they will very materially increase the supply of fresh fish in those ports to which they bring their catches, and in this respect will benefit the inhabitants; at the same time, it must be remembered that this is but one side of the fishing industry and that much material is obtained in the trawl that can be turned, by suitable treatment, to other uses, such as the preparation of dried and salted fish and the manufacture of fish-oil, fish-meal and even fish-manure. In the past, the bulk of the fish guano that is prepared in the Province of Madras is exported, through Ceylon, to other countries and particularly to Japan; the value of this export rose, under the fostering care of the Madras Fishery Department, from 188 tons, valued at Rs. 13,648, in 1910-11, to 32,000 tons, valued at Rs. 24,40,000 in 1922-23, and in 1927-28 it had risen even further to 100,000 tons. If the Japanese trawling in the Bay of Bengal proves to be a success, it is highly probable that in the very near future there will be a marked falling off in the sales to Japan of these Indian fishery products, to the great detriment of the Madras fishermen.

THE present Japanese invasion of Indian waters appears to have commenced in 1935; but its origin can probably be traced back to several years earlier. In 1929-30 the Japanese commenced a surreptitious exploitation of the *Trochus*-shell beds of the Andaman and Nicobar Islands by divers working from motor-boats that were based on Singapore, and this increased to such an extent that the Government of India appointed a fishery research officer in 1931. Unfortunately, owing to lack of proper supervision, undersized shells were fished and, in the absence of any patrolling vessel, grounds that were supposed to be closed were poached, while considerable poaching on the authorized grounds was carried out by unlicensed vessels: in consequence, the shell-beds were rapidly decimated and will take many years to recover. Some of these motor-boats brought with them their fishing nets, and an experiment carried out off Port Blair showed that these nets could be used in these waters with very considerable success, one boat after an absence of two days returning with a catch of about 1½ tons of fish. The natural resources of the ocean are everywhere open to all nations outside the three-mile territorial limit, but unless adequate patrolling of these Indian coastal waters by fishery-protection vessels is carried out—and in view of the great length of coast-line involved this would seem to be impossible—Japanese trawlers will certainly exploit the inshore waters, should experience prove that they are profitable trawling-grounds. A comparison of the various species of fish brought to market by the local fishermen of Akyab in Burma and Puri in Orissa, on opposite sides of the Bay of Bengal, with those taken by the *Golden Crown*, reveals that a large percentage are identical. These local inshore fishing-grounds extend out from the coast for distances varying from about five miles up to as much as 10-15 miles; thus, even were the territorial limit of three miles strictly enforced for these trawlers, there can be little doubt that such trawling by Japanese vessels will affect adversely, and perhaps seriously, the Indian coastal fishing industry.

National Institute of Sciences of India

PROF. M. N. SAHA informs us that the Government of India has decided to make a grant-in-aid of Rs. 6,000 per annum to the National Institute of Sciences of India, Calcutta, with effect from 1937-38. The grant will be subject to the following conditions: (1) Provision should be made for a nominee of the Government of India on the Council of the Institute. (2) An annual report of the working of the Institute, together with a duly audited statement of accounts, should be furnished regularly to the Government of India. (3) The Institute should tender advice on any scientific problems which may be referred to it by the Government of India and discharge any other functions which may be assigned to it by the Government of India. No provision exists in the current year's budget of the Central Government for this grant. It is proposed, however, to include a sum of Rs. 12,000 in the budget estimates for 1938-39.

on account of the grant for the year 1937-38 and 1938-39 and, subject to the vote of the Legislative Assembly, steps will be taken to pay this amount early in the year 1938-39.

Devices for Fighting Fires

In the High Tension Conference held in Paris in June interesting discussions took place as to the relative merits of fire-fighting equipment. In Part 2 of an article by T. Rich in the *Electrician* of July 16, the latest opinions of French engineers on the devices used in practice are given. For protecting transformers and alternators of large output, alarm indicators are used as well as extinguishing appliances. They are of the fixed type which operate automatically when the station has no attendants and when the generators are very large. The movable apparatus generally used consists of extinguishers, boxes of sand, blankets and water jets directly connected to the mains or to a foam generator. Gas masks, smoke fans and emergency lamps are auxiliary apparatus. Portable extinguishers are only used for very small fires. It is important that the material used should be a bad conductor of electricity, as small fires make a close approach necessary and the jet may give a dangerous shock. Carbon tetrachloride has high extinguishing powers and it is not a good conductor. But at high temperatures it decomposes into a gas that is corrosive and poisonous, so that a gas mask is desirable although it entails a loss of time. Methyl bromide is generally thought to give out less poisonous fumes but it is expensive. Saline solutions with a base of potash have a high extinguishing capacity but they are dangerous to use as the jet is a conductor. Carbonic acid snow is not such a good extinguisher but its use entails no danger to personnel. It can be used without cutting off the current, and so is useful in the case of small fires, but the risk of re-ignition is serious. Fire-resisting blankets are used to put out burning clothes on persons. They should be kept in metallic cases with anti-moth material and a window should be put in the case to ensure that the contents have not been borrowed for other purposes. 'Atomized' jets which work under a high pressure have been found useful both in putting out oil fires and cable fires. For hoses rubber is better than woven material. Each 'fire' point at an electric station should have a sand box with wood shovels, a gas mask and a lantern.

Annual Report of the Ministry of Health

THE eighteenth annual report of the Ministry of Health, 1936-37, has been recently issued (H.M. Stationery Office. 5s. net). It consists of an introduction and seven chapters, and includes the work of the Welsh Board of Health. The death-rate was 9.2 per thousand, the death-rate of infants below one year 59, and the maternal mortality rate 3.81, per 1,000 live births. Tuberculosis mortality was the lowest on record, being a rate per million living of 583 for pulmonary, and of 109 for non-pulmonary, tuberculosis. Notifications of diphtheria were 7,290 less than for 1935, but still considerably in excess of

those for 1933. Of enteric fever, 2,493 cases were notified, compared with 1,750 in 1935, the increase being mainly due to the epidemic last summer at Bournemouth, Poole and Christchurch. Public analysts examined 146,438 samples of food and drugs—a record number—of which 7,802 were reported against. Of this total, 80,082 were samples of milk and 7,588 those of butter. Under slum clearance and rehousing, up to the end of last year 100,355 houses had been demolished and 127,553 houses built to replace them, this being the fourth year of the five years' plan. This year, general progress in town and country planning, especially in preserving the countryside, has markedly increased. No less a sum than £65,000,000 of Exchequer money was spent in 1936 on services administered by the Ministry, but only £2,200,000 of this was expended on central administration.

Apparatus for Testing Petroleum and Related Products

A CATALOGUE of scientific apparatus is necessarily a classified list of separate items and to repay reading must be clearly printed, attractively set out, adequately illustrated and up to date. Messrs. Gallenkamp and Co.'s catalogue (No. 96A, 1937 Edition) listing apparatus for testing petroleum, tar, asphalt and their products, fulfils all these requirements and will be of definite interest to those engaged in the examination of these substances. The listed apparatus includes types standardized for routine tests by the Institution of Petroleum Technologists, the Standardisation of Tar Products Test Committee, the British Standards Institution and the American Society for Testing Materials, as well as many other special forms which for one reason or another have not been so standardized. The drawings, in general, have been executed with due attention to detail, although on p. 35, an unsuitable type of ring burner has been included in the diagram of the apparatus for the determination of water in asphaltic substances; on p. 43, the position of the thermometer in the R and B softening point apparatus is incorrect and on the same page, the K and S softening point apparatus depicted is not the standard type specified by the S.T.P.T.C. The arrangement of the subdivisions is at present somewhat haphazard, necessitating frequent reference to the index; it could be improved by the substitution of an alphabetic order on the lines of the Institution of Petroleum Technologists' hand-book. Despite these defects, the catalogue will be appreciated by technologists specializing in the fields indicated in the title.

Natural Colour Eclipse Photography

WE have received from Mr. Edward R. Hewitt, of 127 East 21st Street, New York, a correction of the statement, quoted in NATURE of March 13, that the *National Geographic Magazine* of February contained the first natural colour photograph of a total solar eclipse ever reproduced. Mr. Hewitt informs us that the *Scientific American* of April 1925 reproduced a colour photograph, made by him, of the total eclipse of January 24, 1925, and has sent

us a copy of the reproduction. Mr. Hewitt, in 1925, used Autochrome plates specially sensitized by himself, and his camera had a focal length of 8 ft. Dr. Gardner, in 1936, used Dufay colour plates and a camera of 19-ft. focal length. Owing to the greatly differing circumstances, any detailed comparison of the two pictures would be invidious. The picture Mr. Hewitt has sent us is about a tenfold enlargement of the original, and shows a yellow coronal image extending to about a fifth of a solar radius from the limb, so that on the original plate the coronal image can only have been about 0.6 mm. across, whereas Dr. Gardner's picture was reproduced at about actual size and showed a corona extending to about a solar radius or about 20 mm. on the original plate. In view of the low resolving power of colour plates, it would be absurd to expect much recognizable detail on the 1925 plates, and indeed there is only a suggestion of coronal form, and the colour is presumably in error, but the photographs had the value of demonstrating that colour plates could be made sensitive enough to photograph a total eclipse.

Plant Diseases and Pests of India

Science and Culture contains an interesting review of "Some Plant Diseases and Pests of India and their Control" by Amil Mitra (2, Nos. 8 and 9, Feb. and March 1937). The paper should serve the useful purpose of directing attention to the serious nature of plant disease, for it includes succinct references to the monetary or percentage losses occasioned by many fungi and insect pests. These are sufficiently convincing. The world's loss through the activities of various rust diseases of wheat is estimated at about £60,000,000, and India bears about £4,000,000 of this. A smut disease of the Jowar crop, caused by the fungus *Sphacelotheca sorghi*, causes a loss of 20-25 per cent, and in the Bombay Presidency alone, this means a cost of two crores of rupees (about £2,000,000). Sugar cane mosaic, caused by a virus, often lowers the yield of sugar by 30-35 per cent, whilst a wilt of the pea crop caused by the fungus *Fusarium Vasinfectum* seems to cause the highest percentage damage, for more than half the crop is often lost as a result of its depredations. The review mentions the particular methods of control for each disease or pest, which have been found most effective in practice. A few insect and eelworm enemies are mentioned, but the main emphasis of the paper is that of a mycologist.

Journal of Parapsychology

AN introduction by Prof. Wm. McDougall gives reasons for the publication of a new journal, the *Journal of Parapsychology*, and making clear its object. Throughout the ages, people have asked: Are mental processes always and everywhere dependent upon material and physical organizations? What are the relations of mind and matter? Do the volitions and beliefs of men make any difference to the historical course of the events of the world? Is the physical co-extensive with the mental and the powers and potentialities of mind to be defined by

the laws of the physical sciences? For the most part, the psychology studied in the universities has not concerned itself experimentally with these problems, and such work as has been undertaken has generally been the leisure-time pursuit of interested amateurs. Prof. McDougall thinks that all those phenomena vaguely denoted by the phrase, 'psychical research', ought to be the study of trained scientific workers in the universities, both in the interests of the development of knowledge and of the public. A beginning was made at Duke University in 1930 to study what the researchers called 'extra-sensory' perception. In order that the experiments made in one laboratory may be repeated by other workers, it seemed desirable that there should be a journal. The need for multiple repetitions by different observers of all experiments purporting to give positive results is greater in this field than in others. The word parapsychology is chosen to denote the more strictly experimental part of psychical research. The journal is published quarterly, and the first number is dated March 1937 (Durham, N.C.: Duke University Press. Subscription 3 dollars a year).

Cist Burial at Blaydon-on-Tyne

AN interesting example of a cist burial is reported from Blaydon-on-Tyne (*The Times*, Aug. 6). The discovery was made by workmen digging in a sand-pit, who uncovered the broken upper slab of the chamber. The dimensions of the cist were 3 ft. 8 in. in length, 2 ft. 3 in. wide and about two feet in depth. The interior was filled with sand, but among the contents were found a human skull and bones of the skeleton. With them was a flint knife about two inches in length. The site was visited and the cist examined by Miss G. M. Scott, assistant curator of the Hancock Museum, Newcastle, Mr. W. Bulmer, of the Corbridge Museum, and other authorities of the locality, in whose opinion the find belongs to the Bronze Age and is to be assigned, notwithstanding the absence of the beaker which might be expected, to a date at about 1500 B.C. A burial with skeletal remains of a somewhat earlier date was found on Summerhill, not far away, seven years ago and is on view as reconstructed in the Hancock Museum.

National Museums of Natural History

FREQUENT visits from, and even interchange of, the staffs of the larger museums of the British commonwealth of nations, as referred to in an article in *NATURE* of January 9, has evidently the strong approval of Mr. Frederick Chapman, the well-known authority on the Foraminifera, who has written to us from Melbourne on the subject. The 'Australian Museum' is situated at Sydney and there is the 'Melbourne National Museum', which from the wealth of its collections, especially palaeontological, must be regarded as also of the highest rank. It is immaterial that one museum may be richer than the other in some sides of biology, for such must always be the case. The important matter is that tightening of the bonds between all the museums in question, which has the approval of the Museum Association

Australia. Further, we understand that a representative of this Association was deputed to discuss this with the trustees of the British Museum this summer. When can we expect to hear the result of this discussion?

Research at Armstrong College

FROM Armstrong College, Newcastle-upon-Tyne, we have received a report for 1935-36, somewhat elaborated, by the Standing Committee for Research. The importance of some of the work accomplished with the help of the Committee's small subventions (twenty-six grants amounting in the aggregate to 846) is well brought out in an eighteen-page summary prefixed to the individual reports of the recipients and list of publications. An obvious advantage of a fund such as that administered by the Committee, appropriated in advance to specified fields, is that its administration compels representatives of different departments to take an interest in research in each other's fields, and this promotes inter-departmental collaboration in research, instances of which are cited in the report. Of the role of philosophy in the University, the Committee takes a liberal view, for it refers to works emanating from the College's Department of Philosophy as "original contributions towards the formation of that background of knowledge which forms, or should form, the background of university education".

American Documentation Institute

THE American Documentation Institute was incorporated at a meeting in Washington on March 13 as a corporation "not for profit" but for educational, literary and scientific purposes. The first objective of the new organization is to develop and apply the new technique of microphotography to library, scientific and other material. This national organization was foreseen as an outline of the documentation activities of Science Service when they commenced in July 1935. Bibliofilm Service has been conducted by Science Service in co-operation with the Library of the U.S. Department of Agriculture as a service to research workers, and in auxiliary publication through microfilm, leading academic and scientific journals have co-operated.

Cytological Technique

A SHORT but useful pamphlet giving an "Outline of Cytological Technique for Plant Breeders" is issued by the Imperial Bureau of Plant Genetics (1s. 6d.). Genetics and cytology have become so intimately interwoven in their results that every plant breeder needs to have some knowledge not only of chromosome investigations but also of the methods of cytology. The various techniques involved are sufficiently exacting if satisfactory results are to be obtained. This pamphlet gives an account of the paraffin method, the smear method and a short statement containing the essentials of technique in the use of the microscope, the methods being based mainly on the schedules in use at the John Innes Horticultural Institution, Merton.

Microscopy: the Quekett Microscopical Club

WATSON'S *Microscope Record* of May (No. 41), among other matter, contains an account by Mr. J. F. Stirling of the microscope used by John Dalton, now in the possession of the Manchester Literary and Philosophical Society, and an article by the editor on the appropriate eyepiece to use with certain objectives. Two new species of Bdelloid Rotatoria are described by Mr. W. E. Garner in the *Journal of the Quekett Microscopical Club* of April (Ser. 3, 1, No. 7, p. 280). Mr. W. E. Watson Baker is the new president of the Quekett Club, which is holding its annual conversazione on October 12 in the rooms of the Royal Society at Burlington House.

Conference on Protection against Natural Disasters

THE first "Conférence internationale pour la protection contre les calamités naturelles" is to be held at the Paris Exhibition on September 13-17. The following titles of sections of the Conference indicate its scope: vulcanology and seismology, meteorology, zoology and epidemiology, economic and social crises (fires, famines), assurances. The organizers of the Conference are the Commission Française d'études des calamités, one of a dozen such national commissions which owe their existence to the initiative of the editorial board of the scientific periodical, *Matériaux pour l'étude des calamités*, established in 1924 by M. Raoul Montandon. In that year the Italian commission was formed. Its president is Giovanni Ciralo, who is also president of the Union internationale de secours founded by the League of Nations in 1927, when the French commission was formed. Later, similar bodies were established in Austria, Belgium, Bulgaria, Chile, Czechoslovakia, Greece, Hungary, Italy and Switzerland. Others are in course of formation in Russia and Yugoslavia. The opening session will be presided over by the Under-Secretary of State for Scientific Researches and the closing session (to be followed by a reception at the Hôtel de Ville and a banquet) by the Minister for the Colonies. Admission to membership of the Conference involves payment of a fee of 100 francs, exclusive of the charge of 40 francs for participation in the banquet. Membership will carry the right of free entry to the Exhibition during the Conference. The address of the secretariat is: Laboratory of Applied Entomology, 45 bis, rue de Buffon, Paris, 5^e. The secretariat will, if desired, reserve bedrooms for members.

Comet Finlér

PREDICTION for the place of Finlér's Comet for the next three weeks is given in Announcement Card No. 421 issued by Harvard College Observatory. The ephemeris is based on a parabolic orbit computed by Dr. A. D. Maxwell of the University of Michigan. The time of deduced perihelion passage is August 15.76946 U.T. This comet was discovered on July 4 last by Finlér at Zurich; it was then of the 7th magnitude. It is now possible to locate the comet with the naked eye. The following predicted positions at 0^h U.T. show that the comet will pass 3° or 4°

west of the bright star, Arcturus, between August 22 and 23. In the latitude of London, Arcturus sets in the north-west about an hour after midnight (Summer Time) in the middle of the month.

Announcements

THE following research fellowships in tropical medicine have recently been awarded by the Medical Research Council: *Senior fellowship* to Dr. Frank Hawking, assistant lecturer in pharmacology, Welsh National School of Medicine, Cardiff; this is tenable for three years, for investigations to be made mainly in the tropics. Dr. Hawking will work in Africa on the chemotherapeutic treatment of sleeping sickness. *Junior fellowships*: D. A. Cannon; J. L. Dales, assistant pathologist, Royal Hospital, Sheffield; I. W. MacKichan, house surgeon, London Hospital.

ON the recommendation of the Agricultural Research Council the following awards of agricultural research scholarships, studentships for research in animal health and veterinary scholarships have been made by the Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland: P. J. Faulks (plant physiology), R. S. Russell (plant physiology), F. H. Malpress (nutritional chemistry), J. Wilson (plant genetics), G. H. L. Dickier (entomology), J. W. Whittick (animal pathology), F. D. Asplin (poultry diseases), Miss K. M. Massey (poultry diseases).

THE following awards for 1937-38 have recently been made by the Salters' Institute for Industrial Chemistry and approved by the Court of the Salters' Company: a fellowship has been renewed to L. M. Baxt, Imperial College; fellowships have been awarded to R. H. Freak, University of Oxford, A. J. Shorter, University of Birmingham, J. L. Tuck, University of Manchester, and S. H. Wade, Imperial College of Science and Technology; the Salters' Institute has also awarded forty grants-in-aid to young men employed in chemical works in or near London to assist them in their studies.

DR. J. ANDERSON has been appointed representative of the Scottish Beekeepers' Association on the Bee Research Committee that advises it in regard to investigations on bees carried out at Rothamsted. Dr. Anderson is well known for his special knowledge of bee problems and for his admirable work in Scotland in applying science to the solution of the beekeepers' difficulties.

EIGHT honorary memberships of the Engineering Institute of Canada were conferred at the semi-centennial meeting of the Society held in Montreal recently. The engineers honoured include Sir Alex-

ander Gibb, president of the Institution of Civil Engineers; the Hon. C. D. Howe, Minister of Transport, Ottawa; the Hon. Grote Stirling, former Minister of National Defence, Kelowna; Prof. R. W. Angus, professor of mechanical engineering at the University of Toronto; Dr. George Harriek Duggar, a past-president of the Engineering Institute of Canada and chairman of the Dominion Bridge Company, Montreal; and Mr. S. J. Hungerford, chairman and president of the Canadian National Railways, Montreal.

DR. JOHN K. SMALL, chief research curator of the New York Botanical Garden, who has described the proposed Everglades National Park on p. 26 of this issue, has sent us sixty papers, of diverse botanical interest, published in the *Journal of the New York Botanical Garden*, and extending over a period of twenty years. The papers demonstrate great field activity on the part of the author, especially in plant morphology and ecology. It is interesting to note that Dr. Small has published about a hundred reports on explorations and fourteen descriptive floras concerned chiefly with the south-eastern United States. Copies of these publications can be obtained from the Science Press Printing Co., Lime and Green Streets, Lancaster, Pasadena.

DR. ADOLF BUTENANDT, director of the Kaiser Wilhelm Institute for Biochemistry, has been awarded the Scheele Medal of the Chemical Society of Stockholm.

GEHEIMRAT PROF. CARL BOSCH has been elected president of the Kaiser Wilhelm Society for the Advancement of Science in succession to Prof. Max Planck.

THE Gluge Prize of physiology of the Belgian Royal Academy of Sciences has been awarded to Prof. J. J. Bouckaert of the University of Ghent.

DR. VICTOR G. HUBER has been awarded the Medal for Distinguished Service of the Pennsylvanian Society of New York in recognition of his medical research work under the auspices of the Rockefeller Foundation.

THE sixteenth American Congress of Physical Therapy will be held in Cincinnati, Ohio, on September 20-24 at the Netherlands Plaza Hotel, under the presidency of Dr. William Bierman of New York. Further information can be obtained from the editorial and executive offices of the Congress, 30 North Michigan Avenue, Chicago.

AN International Congress of the Scientific Press organized by the Professional Syndicate of the Scientific Press will be held in Paris on October 7-9. Further information can be obtained from M. Toutain, 25 rue du Four, Paris.

ERRATUM. In NATURE of August 7, p. 229, the date of the erection of the Roman bath at Leicester should be, obviously, A.D. and not B.C. as stated.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 283.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Lecithinæmia following the Administration of Fat

ABOUT two hours after the administration of a meal containing fat, the fat content of the blood begins to rise. Bloor¹ found that when olive oil is administered to a dog, besides an increase in the neutral fat content of the blood an increase in its lecithin content also takes place. The average increase was found to be about 20 per cent. A maximum is reached after four hours. Bloor was inclined to ascribe the lecithin formed after the administration and resorption of the neutral fat to a synthesis occurring inside the red blood corpuscles. Other explanations might, however, be suggested as well, namely: (1) The lecithin is synthesized in the intestinal mucosa and absorbed into the blood. (2) The synthesis takes place, after the resorption of neutral fat, in the liver, or somewhere else outside the intestinal tract. (3) The increase in the lecithin content of the blood is due to mobilization of preformed lecithin after the resorption of the neutral fat.

To decide which of these suggestions is to be accepted we repeated Bloor's experiment, but administered simultaneously with the oil-labelled (radioactive) phosphorus in the form of sodium phosphate. In the case denoted by (1) the additional blood lecithin should contain chiefly labelled phosphorus; in case (2) the additional lecithin should contain only small amounts of labelled phosphorus; in case (3) the additional lecithin should contain ordinary phosphorus only.

We determined the normal P present in the blood lecithin, which was extracted by the usual procedure, by the method of Fiske and Subbarow, and the labelled P by means of a Geiger counter. While, as seen in the table, the lecithin phosphorus content of 100 c.c. of blood increased by 2 mgm. four hours after administering the oil, that of labelled P only increased by 0.028 mgm. We must, furthermore, take into account the fact that half the labelled phosphorus administered two hours before the oil produced 0.028 mgm. labelled lecithin P during that time. We must therefore deduct 2×0.028 mgm. from the 'oil effect' of 0.096 mgm., obtaining 0.04 mgm. per 100 c.c. of blood for the maximum value of the 'oil effect'.

An important objection can, however, be raised to our conclusion; it may be argued that the intestinal tract might contain large amounts of phosphorus other than the labelled phosphate administered by us, the presence of which must be accounted for when carrying out the above calculation. To investigate this point and to ascertain to what extent the labelled phosphorus was resorbed, we killed the dog after the last experiment, the results of which are seen in the table. We washed the intestinal tract with water and determined both its total P content and its labelled P content. We

found by activity measurements 39.6 mgm. labelled P and by chemical determination 175 mgm. normal P. Within six hours as much as 260.4 mgm. of the 800 mgm. administered to the dog was thus resorbed. The 135 mgm. non-labelled phosphorus got into the intestine, presumably along with the digestive fluids, so that the 40 mgm. labelled P were 'diluted' to 175 mgm. We determined also the total acid-soluble phosphorus content of the intestinal mucosa; it was found to amount to about 40 mgm., bringing the above figures up to 215 mgm. But even if we make the assumption that this dilution was present during the whole of the resorption process we should get the result $5.2 \times 0.064 = 0.21$ mgm. per cent lecithin P, while an increase of 2 mgm. per cent was found in the blood lecithin P.

Time in hours	Labelled P given in mgm.	Lecithin phosphorus found in 100 c.c. blood		Labelled total P found	
		Total	Labelled	In 100 c.c. blood	In the total blood of the dog
0	150	—	—	—	—
2	150 (+50 gm. oil)	16.0 mgm.	0.028 mgm.	1.03 mgm.	6.18 mgm.
4	—	15.5 "	0.048 "	2.03 "	12.18 "
6	— (250.4 mgm. resorbed)	18.0 "	0.066 "	2.00 "	12.00 "

It is of interest to compare the labelled P content resorbed with that actually found in the blood stream of the dog. Six hours after the beginning of the experiment, as is seen in the table, only 4.6 per cent of the amount resorbed was found. This result illustrates beautifully the great rapidity of the phosphorus exchange in the body. As observed by us in numerous cases, the individual phosphorus atoms present in the blood stream exchange their places rapidly with others present in the different organs. For this reason we can conclude with certainty that during our experiments the ratio labelled phosphorus to ordinary phosphorus must have been appreciably higher in the intestinal mucosa than in the blood.

The only moderate increase in labelled phosphorus in the blood lecithin after administration of oil, an increase which nevertheless in all our experiments exceeds the increase observed after the radioactive phosphorus was administered alone, leads to the conclusion that during the absorption of neutral fat, lecithin is formed outside the intestinal tract. A comparatively rapid formation of labelled lecithin in several organs in the course of normal metabolism has in fact recently been observed².

Some of the labelled phosphorus used in our experiments was prepared by us from sulphur under the action of neutrons emitted by a radium-beryllium

mixture most kindly put to our disposal by Prof. Niels Bohr, and some of it was a generous gift from Prof. Lawrence, of the University of California. We should also like to express our best thanks to Mr. A. H. W. Aten, jun., and Miss Hilde Levi for their assistance in this work.

A New Source of Vitamin A

IN the course of a study of the mode of occurrence and distribution of vitamin A, we have found that the viscera (excluding the livers) of halibut yield abnormally rich oils (see table).

VITAMIN A IN HALIBUT

Weight of fish (kgm.)	Weight of liver (kgm.)	Weight of 'viscera'* (kgm.)	Weight of liver oil (gm.)	Weight of 'visceral' oil (gm.)	Weight of vitamin A		Percentage† vitamin A	
					In liver (gm.)	In viscera (gm.)	In liver oil	In visceral oil
45.4	1.03	1.67	203	36	3.84	2.88	c. 2.0	8.0
45.4	0.54	1.47	70	27	1.53	1.61	2.2	5.6
28.6	0.40	0.76	34	15	2.1	1.05	6.3	7.0
23.6	0.34	0.85	—	15	—	0.9	c. 4.5	6.0
26.9	0.51	1.04	—	17	—	0.48	0.33	2.8
36.3	0.91	1.05	205	20	0.22	0.32	0.11	1.6

* In this table the term 'viscera' refers only to stomach, mesentery and intestines.

† Percentage is calculated on the basis
for vitamin A, so that for an
8 per cent oil we have —

1%	620 mμ	5,000
1cm	583 mμ	2,600
1cm	328 mμ	1,600

The fish were caught in Shetland waters in May this year and their stomachs were free from food.

The viscera are normally thrown into the sea although they may contain, as in these cases, as much vitamin as the liver, and may yield more potent oils.

In the eye, Wald has shown that vitamin A forms a complex with protein. In order to test whether a similar complex occurs in liver, we have attempted to extract liver oils without denaturing proteins. In a number of instances the oil obtained by the use of non-polar solvents contains much less vitamin A than the oil obtained in other ways from the same liver. The phenomenon is best shown with livers poor in vitamin, but even in halibut, part at least of the vitamin A is not present in oil solution.

This work is being carried out under the auspices of the Medical Research Council and the Food Investigation Board.

Intensity Ratios of the Hyperfine Structure Components of the Resonance Lines of Potassium

IN view of conflicting evidence as to the sign of the nuclear spin of potassium 39, it was decided to make a quantitative investigation of the intensities of the hyperfine structure components of the resonance lines. The method used was similar to that used by the authors for the hyperfine structure of the resonance lines of silver¹. The absorption produced by an atomic beam of potassium in the resonance line given by a potassium lamp similar to that previously described was observed by means of an etalon of 5 cm. plate separation, with heavily silvered plates. Under these conditions, the adjacent orders of the emitted lines are well separated from each other, and the hyperfine structure can be observed as a narrow absorption doublet. In order to measure intensities, a photograph is made first of the emitted light without absorption, and then with absorption; the reduction in the logarithmic intensities by the absorption line give their respective absorption coefficients, and the ratio of these the required intensity ratio.

The collimation of the atomic beam was 1:8; the absorption of the hyperfine structure was observed best when the temperature of the potassium was about 150° C. (v.p. = 5×10^{-4} mm. mercury) the absorption in the weaker component of the line $4S_{1/2} - 4^2P_{1/2}$ being about 60 per cent. Seven determinations of the intensity ratio were made for this line; the values were 1.44, 1.44, 1.44, 1.38, 1.43, 1.48 and 1.45, the mean being 1.44; the component of longer wave-length being the stronger. For the line $4S_{1/2} - 4^2P_{3/2}$, four determinations of the intensity ratio were made, the values being 1.52, 1.42, 1.40 and 1.45, mean 1.45; the component of longer wave-length was the stronger. A photometer trace of this line is shown in Fig. 1, three orders being shown.

← Wave-length

Fig. 1.

a, LIGHT SOURCE ONLY; b, ABSORPTION OF ATOMIC BEAM.

It was observed that when the density of the atomic beam was increased twenty times by raising the temperature of the potassium to 200° C.

(r.p. = 7×10^{-8} mm.) the short wave-length component in both resonance lines became considerably broadened, its width being about 0.012 cm^{-1} , that of the other component being about 0.008 cm^{-1} .

According to Millman and Fox and Rabi² the nuclear moment of K39 is $3/2$. The observed intensity ratio is in agreement with this if it is assumed that both the hyperfine structure components of K41 lie on the weaker component of K39; in this case the observed intensity ratio should be $1.67 / (1 + \frac{2.67}{14}) = 1.40$, the total intensity of K41 being $1/14$ of that of K39. This is in good agreement with the observed value 1.44. The broadening of the weaker component at very high densities is strong evidence in favour of this interpretation, as the separation of the two high-frequency components of K41 is 0.00853 cm^{-1} according to Manley³. The spreading out by this structure of the absorption of K41 could reduce its influence on the intensity by about one third, the calculated intensity ratio becoming 1.46, and thus in even better agreement with the observed. No trace of absorption due to K41 outside that due to K39 was found with 5 cm. and 2 cm. etalons when the atomic beam was twenty times as dense as that needed to give 50 per cent absorption by K39; and the intensity of the background was varied by giving exposures up to 20 times normal.

On the above view the centre of gravity of the components of K41 overlaps the weaker component of K39; this indicates a violet isotope shift of K41 equal to about 0.009 cm^{-1} ; the normal centre of gravity shift is theoretically 0.009 cm^{-1} .

It is thus shown that the spectroscopic determination of the nuclear moment of K39 is in complete agreement with those made by Rabi and others; the sign of the magnetic moment is positive⁴, and the value of the spin $3/2$.

In a previous note⁵, we stated that the short wave-length hyperfine structure component of $4S_{1/2} - 4^3P_{1/2}$ appeared stronger; this discrepancy can be explained; for the photometer traces of the absorption in which this was observed were made from photographs (intended for measurement of distance of high-frequency components and not for intensity measurements) made with an etalon of 10 cm. plate separation; under these conditions the emitted lines in adjacent orders overlap each other, so that in the position where the absorption was observed there is unabsorbable light from the wing of the emitted line in the adjacent order. The density of the atomic beam was very high (temperature of potassium $220^\circ \text{ C}.$) so that the absorption was almost complete, and the light transmitted was due to the overlapping wing, and had no significance as to the intensity ratio of the high-frequency components.

The observation of Fisher⁶ that the short-wave components appear stronger in an excited atomic beam can perhaps be explained by self-absorption; moreover, it has been observed by K. W. Meisner⁷ that the long wave component is the stronger in an excited atomic beam.

Expulsion of Neutrons from Lead by Cosmic Rays

A NEUTRON counter was made of a brass tube 10 cm. long and 1 cm. in diameter, the inner surface being coated with a thin film of borate a few microns thick. The axial collector of the ionization chamber was directly connected to a set of the improved linear amplifier system, which was so carefully mounted that the counting system was perfectly free from the mechanical and electrical disturbances of the surroundings, and gave only two to four clear, natural kicks in an hour. By a series of control experiments with neutrons from a radium-beryllium source (of 10 mgm. radium), it was found very reliable for observing slight variations in the number of kicks under various experimental conditions.

Now when the counter was placed inside a lead chamber 50 cm. long and 10 cm. thick (the dimensions are shown in Fig. 1) the number of kicks was found to increase to about 7 per hour, while it amounted to about 15 per hour when the space around the chamber was filled with paraffin.

Fig. 1.

These observations were carefully done intermittently for half a year. Though it was difficult to maintain the constant reliability of the counting system for a long duration of time (the results for different dates were sometimes markedly different) most of the results obtained in good conditions were found to lie within the following extreme values:

	Natural kicks outside the chamber	Kicks inside the lead chamber without paraffin	Kicks inside the lead chamber filled with paraffin	Kicks outside the chamber but within paraffin
Min.	2 per hour	4-6	9-13	Less than those counted in the lead chamber without paraffin
Max.	4	7-9	18-20	

(Boron-surface: 10 cm. in length and 1 cm. in diameter.)

This result shows that a number of fast and slow neutrons are produced by the action of cosmic rays in lead (or less probably in iron or in paraffin).

At first it was suspected that they were liberated at the instant of the production of a 'shower' in lead. But the remarkable Wilson chamber photograph taken by Blackett⁸ showing the disintegration of an atomic nucleus into heavy particles by cosmic

rays, and the interesting research on the general nuclear photo-effect reported by Bothe and Gentner², suggest to us that a neutron or neutrons may be liberated from a lead nucleus by a cosmic ray photon, presumably accompanying a kind of disintegration into heavy particles (general Chadwick and Goldhaber's effect).

A recent report by Fünfer³ on the existence of slow neutrons in the atmosphere corresponds probably with the existence of the natural kicks in our experiment, which is, however, not sufficiently sensitive to decide the matter.

Electron Diffraction Studies of Oxides formed on Iron

THAT iron oxidized at high temperatures forms a scale composed of three layers, namely, ferrous oxide (below 575° C., does not form), magnetic oxide and ferric oxide is generally known. I have examined oxide films formed on a clean surface of iron exposed to air at various pressures and temperatures, using the electron diffraction reflection method, and have been able to ascertain the condition for the formation of these oxides.

Fig. 1.

The iron specimens, after being etched to remove any polishing effects, were heated to definite temperatures in a highly evacuated tube and then oxidized by introducing air at definite pressures. After an appropriate period of oxidation, the tube was again evacuated as quickly as possible and in the meanwhile cooled in two or three minutes to room temperature. The space lattices of oxides were determined by electron diffraction photographs. The regions where the various oxides are formed are shown in Fig. 1. The duration of exposure has no effect on the resulting oxide except in a few cases.

The facts that lower oxides are formed at higher temperatures under reduced pressures and that prolonged exposure does not elevate the degree of oxidation but is manifested only in the increase of scale thickness are interesting phenomena indeed. These

phenomena lead us to the suggestion that iron atoms migrate more vigorously towards the surface with rising temperature and check any further oxidation of the lower oxides.

Only the oxide of the structure of Fe_3O_4 type is obtainable below 340° C., and considering other parts of the diagram this oxide was concluded to be $\gamma\text{-Fe}_2\text{O}_3$. The invisible films¹ of passive iron and of the iron polished in air and the oxide film² formed in air below 200° C. were recently concluded to be $\gamma\text{-Fe}_2\text{O}_3$. These two cases are included within the $\gamma\text{-Fe}_2\text{O}_3$ region of the diagram.

In other investigations³, the transition point between $\gamma\text{-Fe}_2\text{O}_3$ and $\alpha\text{-Fe}_2\text{O}_3$ was indistinct; but in this work it was ascertained that the point lies almost at 340° C., and in the immediate vicinity of this temperature both oxides are formed in almost amorphous state. The ordinarily impossible transition from $\alpha\text{-Fe}_2\text{O}_3$ to $\gamma\text{-Fe}_2\text{O}_3$ was verified to be possible by maintaining the temperature of this nearly amorphous $\alpha\text{-Fe}_2\text{O}_3$ at 330° C.

Specimens heated at 200° C. and 250° C. for a short while produced an extra ring corresponding to 3.4 Å., besides the diffused $\gamma\text{-Fe}_2\text{O}_3$ pattern, which disappeared on further heating. It is hoped that better identification may be arrived at for this unknown primary oxide from a different angle.

Experimental details and technique will be reported in the *Scientific Papers* of this Institute.

I wish to express my thanks to Dr. I. Iitaka and Mr. S. Miyake for their kind guidance.

β -Decay as due to a Neutrino Shower

ACCORDING to the Fermi theory of β -decay, the β -curve representing the number of electrons with a given energy lying in the interval of the transition energy of the nucleus, is governed by a statistical factor which may, however, be deduced in a simple manner as shown by Uhlenbeck and Goudsmit. Experimental curves indicate the existence of a marked asymmetry about half the transition energy of the nucleus, while the statistical factor in the Fermi theory is practically symmetrical.

If we imagine the final process to consist of a shower of neutrinos (the number in the shower depending on the transition energy of the nucleus), with intermediate stages, the asymmetry can receive a simple explanation. Indeed, following the basic transformation pictured by Fermi and assuming the Jordan formulation that a high-energy electron makes a transition to a lower energy state with the emission of two neutrinos the total energy of which is equal to the transition energy of the electron, we can follow the shower production in a way analogous to Heisenberg's theory. The transformations in the β -decay would be

$$N \rightarrow P + e + n, \quad (\text{Fermi})$$

$$\left. \begin{aligned} e &\rightarrow e^I + n^I + n^{II}, \\ e^I &\rightarrow e^{II} + n^{III} + n^{IV} \end{aligned} \right\} \quad (\text{Jordan})$$

resulting in

$$N \rightarrow P + e^{II} + n + n^I + n^{II} + n^{III} + n^{IV},$$

where N , P , e and $\bar{n}$ stand for neutron, proton, electron and neutrino. The electron e may further undergo a Jordan transformation depending on its energy in the field of the nucleus. The number of electrons with less than half the transition energy of the nucleus would be greater than that of those with energy greater than half the transition energy as there would be the tendency for the higher energy electron to undergo the Jordan transformation, thus resulting in an asymmetrical curve representing the number of electrons with a given energy.

An Inexpensive Low-Temperature Thermostat

SINCE the low-temperature thermostats on the market involving an electric refrigerator and temperature regulator are very expensive, it is possible that the following easily constructed apparatus (Fig. 1) may prove of value to many research workers. It was designed for the purpose of subjecting small aquatic animals to a constant temperature over a range of 4° – 10° C. Our present apparatus will maintain a constant temperature $\pm 0.1^{\circ}$ C. Working at 5° C. it will consume approximately $\frac{1}{4}$ cwt. of ice in 100 hours.

Fig. 1.

It consists of two tanks, A a large reservoir containing ice and water, and a small thermostat bath B , both of which are well insulated with powdered cork. A constant temperature in the bath B is maintained by a controlled circulation of water between it and the ice tank through the insulated tubes D and H . This flow is induced by a stream of air bubbles entering via O and streaming up the tube into the cup M , thus raising the level of the water in the latter and causing a flow via H into the ice tank. This is compensated by a back flow of cold water into the bath through D . The air is first cooled by passage through a coil at the bottom of the ice tank in order to prevent subsequent condensation in the thermo-regulator. Any water condensed in the coil is forced up and retained in the trap G . The air can then pass (1) through O to the circulator already described; (2) via the toluol-mercury gas regulator K to the bubbler P ; or (3) direct to the bubbler L . When the

bath temperature falls lower than that required, the air passage through the regulator is open and the tube diameters and taps are so adjusted that all the air is passing into the bath through the bubbler P , thus keeping the water stirred. When the temperature rises as a result of inevitable heat leakage from the air, the bubbler P is stopped by the rise of the mercury in the regulator and the air passes through the circulator and the bubbler L . The result is that the bath temperature is lowered by inflow of cold water while stirring is still maintained. The well-insulated lid of the thermostat bath is in two halves, one, J , into which are inset the thermometer, thermo-regulator and connexions, and the other, H , which is removable in order to give access to the experimental vessels resting on a wire tray. The lid O of the ice tank is weighted and so arranged that it touches the surface of the water at the required level. This prevents alteration in level due to melting of floating ice; that due to specific gravity changes is not sufficient to affect the apparatus and is readjusted when the ice is renewed. Preparatory to addition of more ice, the tubes D and H must be shut while the water is run off through F . An overflow N from the thermostat bath must be provided.

It is, of course, essential that the insulation should be protected against damp from the air or from possible leakage over the edges of the tanks, and that the tube connexions are thoroughly firm and watertight. There is no doubt that the efficiency and sensitivity of our present apparatus could be increased by improvement of certain details, particularly in insulation and in the form of the thermo-regulator. In the absence of a compressed air supply, we have found a Grafton electric aquarium aerator to be thoroughly satisfactory.

The apparatus could be used as a cold aquarium for larger animals if the bath B were made of glass or porcelain and the water circulated between this and a vessel suspended in A and surrounded by the ice and water. It might also be adapted for use at temperatures below 0° C. if brine were used, cooling

being done by the suspension of a vessel in A containing a block of solid carbon dioxide.

Production of Thin Gold Films

IN view of the interest attached to the investigation of the physical properties of thin metallic films, a new and easy method for producing such films of pure gold would seem to have special significance.

Certain organo-gold compounds or their derivatives and, particularly the simplest of such compounds, namely, diethylmonobromogold¹, $[\text{Au}(\text{C}_2\text{H}_5)_2\text{Br}]$, when dissolved in a suitable solvent such as ethanol to which alkali is added, undergo an interesting

decomposition even at the ordinary temperature; the solutions become deeply coloured like those of colloidal gold and in a short time (seven to nine minutes at the ordinary temperatures) gold is deposited as a coherent film.

Brilliant films have been deposited on suitably prepared glass and other surfaces. By reflected light they appear as massive gold and by transmitted light they show the characteristic colours of thin gold films. The films are capable of being polished, but they can be produced in such a manner as to render this unnecessary. The thickness of the films can be varied by altering the conditions of the reaction and the quantities of the reactants.

The necessary starting material being available, the pure gold films are actually more easily produced than those of silver and are much more chemically inert. In spite of their opulent appearance as mirrors, the films of pure gold produced so readily and deposited on glass, etc., may have considerable scientific application.

Spontaneous Electrical Charge of Fine Coal Dust

In the last paragraph of their letter on "Some New Characteristic Properties of Certain Industrial Dusts" in *NATURE* of May 1, Prof. H. V. A. Briscoe and colleagues state: "On several occasions we have found that fine dusts which have become aggregated by settlement or have been for some time exposed to air appear to be much less reactive than when freshly formed. . . ." In this connexion I have obtained interesting evidence which has specific reference to the varying liability of fine dusts to spontaneous electrical charging also dependent upon pre-treatment.

Two samples of the same coal dust were respectively maintained at 80° C. in an oven for 24 hours and 36 hours, the latter being periodically stirred and turned. Representative results of the voltages generated on circulating these dusts were:

	Voltage of generated charge at same capacity	Weight
24-hour sample	344.0	3 gm.
" "	747.5	5 gm.
36-hour sample	270.0	3 gm.
" "	590.0	5 gm.

The ratio of charge generation is approximately 1.25:1 for 24 hour to 36 hour samples.

The residue of the 24-hour sample was then retained in the desiccator at *n.t.p.*, whilst the 36-hour sample residue was further heated in the oven, and the charge divergences were confirmed as follows:

	Voltage of generated charge at same capacity	Weight
Desiccator sample	224.0	3 gm.
Oven sample	64.5	3 gm.

Fresh samples of the same coal dust were then used, and after varying treatments of sub-divided

samples (2 gm. each), were found to generate charge as follows:

Treatment	Voltage of generated charge at same capacity
1. In desiccator overnight	256.9
2. In oven 1 hour	205.4
3. No. 2, after 2½ hours in desiccator	240.8
4. Several days in oven	112.0
5. As No. 4, but turned over many times	87.8

The continuing loss of electrical activity with age of dust is shown.

From 1 and 2, drying with heat produces a lower charge than drying at normal temperature, hence charge variation is probably due to a heating effect, for example, either oxidation or gaseous adsorption on particle surfaces, or both. From 2 and 3, as the regeneration of activity on cooling in desiccator is not likely to be due to reversal of oxidation, it is likely to be due to gas re-adsorbed on cooling in desiccator to replace gas driven off by heating in oven. From 3, 4 and 5, as heating and agitation continue, electrical charge progressively decreases. The decrease, therefore, is probably due to continuing de-adsorption.

It seems, therefore, that the tendency to spontaneous electrical activity of a coal dust decreases with age of dust and with probable decrease of adsorbed films or molecules on the dust particles, and increases, despite age, with increase of such adsorption.

Stereochemistry of the Sterols and the Bile Acids

ALTHOUGH the stereochemistry of the *A* and *B* rings of the sterols and allied substances has been very fully developed, the evidence for the stereochemical configurations of the other rings rests on less secure grounds. The evidence for the *trans* fusion of the *B* and *C* rings rests solely on the requirements of a flat molecule as adduced from X-ray data, while that for the *trans* fusion of rings *C* and *D* is based on

the isolation of the tricarboxylic acid (I) by the step-wise degradation of 12-ketocholanic acid¹ and desoxycholic acid². This acid on pyrolysis gave an anhydride which on hydrolysis furnished an isomeric tricarboxylic acid. It was, therefore, deduced that the former acid had a *trans* configuration, from which it was assumed that the fusion of rings *C* and *D* was originally in the *trans* position. This conclusion would seem to be sound provided that no inversion occurred in the degradation, a loop-hole which cannot be excluded.

Recent work on the relative stabilities of *cis* and *trans* hydrindane derivatives leads to a different

expectation and, in fact, the result of the catalytic hydrogenation of β -ergosterol (II) strongly suggests that rings *C* and *D* are in *cis* relation. Laucht³ has shown quite conclusively that the double bond in this substance occupies the $C_{14:15}$ position. The original stereochemical configuration of the *C* and *D* rings has, therefore, been destroyed, yet, on catalytic hydrogenation in neutral solution⁴ and even in acetic acid⁵ (a solvent known to favour the formation of a *cis* configuration), β -ergosterol yields the same ergosterol as that obtained by the complete reduction of ergosterol. Ergosterol must, therefore, include a *cis* fusion of the *C* and *D* rings. As ergosterol is known to possess the *allo*-cholanolic configuration, it would appear from this line of evidence that the *C* and *D* rings in the sterols and the bile acids are in *cis* relation also.

This result also supplies confirmatory evidence of the *trans* fusion of rings *B* and *C*, since, in the wandering of the double bond from ring *B* to ring *D*, the former two rings would be expected from known analogies to adopt their more stable configuration. This is further supported by the fact that inversions of 7-keto derivatives analogous to the facile isomerization of dehydrohydroxycholeic acid to 8:6-diketo*allo*-cholanolic acid have never been observed.

The *Cis*-form of Azobenzene

DURING determinations of the solubility of azobenzene, in which a photometric method of analysis was used, an apparent lack of reproducibility was traced to an increase both in the light absorption of standard solutions and in the concentration of saturated solutions, on exposure to light. The increases reached steady values after several days' exposure in a thermostat tank in a north-lit room. The increase of adsorption was shown to be nearly independent of light intensity, solvent and concentration, but was reached much more rapidly in bright sunlight—a few minutes sufficing for a *M*/2000 solution in a glass bottle. The phenomenon, persisting after repeated recrystallization of the azobenzene, seemed consistent only with a reversible formation of a polymer or isomer, both forward and backward reactions being activated by light and the thermal reaction being very slow at ordinary temperatures.

The second form was found to be distributed between immiscible solvents much more in favour of the more polar one than is ordinary azobenzene and a method of separation based on this property was devised. 5 gm. of azobenzene were dissolved in 250 c.c. of acetone and the solution exposed to sunlight for several hours. The following operations were then carried out in dim light. 350 c.c. of water were added, the mixture cooled, filtered and extracted with 40 c.c. of light petroleum. The azobenzene left in the aqueous layer would have been extremely small if the acetone solution had not been exposed to light. That actually remaining was

extracted by chloroform. The procedure was several times repeated and the chloroform extracts united, dried and evaporated down *in vacuo*. The product was crystallized from light petroleum between 25° and -15° C.

Solutions of successive crystal fractions were made up in acetone. The first few fractions had a constant absorption coefficient for the blue light used (that transmitted through a Kodak 'Wratten No. 47' gelatin filter) and this was 2.17 times that of ordinary azobenzene. On exposure to sunlight, the absorption of these solutions fell to a constant fraction, 0.61, of the original value. That of ordinary azobenzene rises on exposure to 1.32 of the original, the exposed solutions thus having identical absorption. It was assumed that the first crystal fractions were the pure second form. The equilibrium mixture would contain, therefore, about 27 per cent of the second form.

The melting point of the second form is at least one or two degrees higher than that of the normal form (88° C.). Successive determinations on the same sample gave melting points progressively lower at first, passing through a minimum at about 35°, and then rising to 88° C. Some thermal reversion may have occurred before the first determination, and the exact melting point is therefore in doubt. Thermal reversion is undoubtedly quicker in the liquid than the solid state, but some reversion had occurred in crystals that had been exposed to strong sunlight. In a sealed tube, with a mercury manometer attached, in which the azobenzene occupied about 1/10 of the enclosed air space, thermal reversion took place at 100° C. without change of pressure.

The polar character of the second form, which proves almost conclusively that it is the *cis*-isomer, a suggestion first due to Prof. S. Sugden, is indicated by its greater solubility, despite the higher melting point, in polar solvents, and smaller solubility in petroleum. Determinations of the dipole moment in benzene solutions, made by Dr. R. J. W. Le Fèvre, give a value of 3.0 Debye units. The apparent moment of the ordinary *trans*-form increased on exposure of a solution to light from zero to 1.4–1.5 while that of the *cis*-form decreased to the same value. The change indicates that the equilibrium solution contains between 20 and 25 per cent of the *cis*-form, in good agreement with an approximate estimate of 21 per cent by the photometric method, this value, in a c. 1 per cent solution in benzene, being somewhat lower than that, 27 per cent, found in much more dilute solution in acetone.

Transformation of Hydrate Cellulose into Native Cellulose

If cellulose is precipitated from solution or liberated from its compounds with sodium hydroxide, the space lattice ($a=8.14$ A., $b=10.3$ A., $c=9.14$ A., $\beta=62^\circ$) differs from that of native cellulose ($a=8.35$ A., $b=10.3$ A., $c=7.9$ A., $\beta=84^\circ$). In this form it is known as hydrate cellulose, although it is in fact of the same analytical composition as the native form, and is free from water. Hitherto it has not been possible to convert one modification directly into the other; it was possible to pass from native cellulose via alkali cellulose to hydrate cellulose, and from this

(as Barry, Peterson and King¹ showed recently) by way of the ammonia compound back to native cellulose. Moreover, Hess and Gundermann² have described the appearance of native cellulose along with hydrate cellulose during the washing out of alkali cellulose at 100° C. We find, however, that it is possible to convert hydrate cellulose directly into native cellulose.

When strongly stretched hydrate cellulose in the form of viscose silk 'Lilienfeld silk' is heated for half an hour in water at 200° C., the X-ray diagram shows interferences characteristic of native cellulose as well as those of hydrate cellulose. The same diagram is obtained after treating viscose with boiling formamide (200° C. for half an hour). If the fibres are heated in formamide to 140° C., less native cellulose is formed than at 200° C.; after half an hour in glycerine at 250° C. the hydrate cellulose is converted almost completely into the native form. If the fibres are left for eight days in water at 200° C., very little more native cellulose is formed than after half an hour.

The same experiments were made with hydrate cellulose obtained by the mercerization of ramie. It was found that under the same conditions less native cellulose was formed from this material than from Lilienfeld silk.

Dry viscose heated for twenty minutes in a high vacuum at 200° C. remains unchanged; but after ten minutes at 300° C. a little native cellulose is formed. Water and other dipole-containing liquids appear to increase the rate of transformation very considerably.

Native cellulose (ramie) after heating for five days in water at 150° C. remains unchanged. We conclude that at least over the range of temperature covered by these experiments *native cellulose is the stable form, and hydrate cellulose the non-stable*.

As already indicated, Hess and Gundermann obtained native cellulose by the action of water at 100° C. on alkali cellulose. We have been able to detect native cellulose in preparations which were washed out at 60° C. If decomposition and washing out take place at 20° C. and the preparation is afterwards heated, no native cellulose is formed even at 100° C. On dipping fibres of alkali cellulose into formamide at 140° C. the product obtained is almost entirely native cellulose. In all these cases, therefore, the temperature necessary for the formation of native cellulose is considerably lower than that required for the transformation of hydrate cellulose as such into the native form.

Isolation of Ascorbic Acid from Urine

HINSHBERG and Ammon¹ have been unsuccessful in an attempt to isolate ascorbic acid from urine. Recently E. C. Noyons² has described a method for the isolation of ascorbic acid from tomato juice involving chromatographic adsorption, and has announced his intention of applying a similar procedure to the isolation of ascorbic acid from urine.

We have been engaged for a considerable time on this problem and have finally isolated from urine a small amount of a crystalline dinitro-phenyl hydrazine derivative which appears to be that of ascorbic acid. Its melting point (269–271 uncorr.) agrees with that of the similar derivative prepared from pure ascorbic acid (m.p. 270–272) and the crystalline forms appear identical. A mixed m.p. with the dinitro-phenyl hydrazine derivative of the pure vitamin shows no depression (m.p. 271–272). The reliability of the m.p. determinations has been checked by taking a mixed m.p. of the 2:4 dinitro-phenyl hydrazine derivative of ascorbic acid and salicylaldehyde (m.p. 249). A very marked depression was observed, both in this case and in another where a mixed melting point of two different hydrazones with very similar melting points was taken.

This work is being continued, and we hope shortly to be in a position to give a more complete account of this investigation.

A Diene Synthesis applicable to the Sterol Group

This method is regarded as the most promising yet adumbrated in that it reduces the problem of the synthesis of cholesterol or its stereoisomerides and analogous substances to the much simpler one of preparing a monocyclic and a bicyclic intermediate. It seems to be especially important that the double bond of cholesterol is placed by this synthetic process in the correct position and that unlike many other diene syntheses the method can be used to introduce the angle-methyl groups.

1-Methyl-2-vinylcyclohexene (I), obtained from the known 2-methylcyclohexenylethyl alcohol by an application of the xanthogenate reaction, condenses with maleic anhydride in benzene solution with the formation of the anhydride (II), m.p. 111.5°. This and the related dibasic acid, m.p. 171°, afforded analytical values tallying with theoretical anticipations.

With crotonaldehyde the diene furnishes an adduct the dinitrophenylhydrazone of which has m.p. 192° and analysis of which agrees with the formula C₁₈H₂₄O₄N₄. The 2:4-dinitrophenylhydrazone of the adduct (III) from the diene and cyclohexanone has m.p. 164° and gives satisfactory figures on analysis.

Fig. 1.

The constitutions of the intermediates now required for the synthesis of substances containing the cholane skeleton are obvious on inspection, and attempts to make some of them are in progress.

Antimicrobial Action of Some Aromatic Compounds

NUMEROUS recent researches have directed our attention to the antimicrobial action of various aromatic amino or nitro compounds containing the following functional groups: sulphamide, $R-SO_2NH_2$; thio, $R-S-R'$; dithio, $R-S-S-R'$; sulphone, $R-SO_2-R'$; thiophenol, $R-SH$; sulphinic acid, $R-SO_2H$. By chemical analogy with the arsenic compounds in which the arsenoxide group shows *in vitro* a very high parasitocidal activity, we have been led to a study of the *para*-substituted aromatic sulphoxides.

Experiments on mice have proved that 4:4'-

diacetylaminodiphenyl sulphoxide (m.p. $292^\circ C$. uncorr.) and also other sulphoxides, symmetrical or asymmetrical, containing the groups OH, NH, or NO, in the *para*-position, administered by mouth, show an extremely high curative activity not only against *Streptococcus*, but also against experimental gonococcal infection.

Points from Foregoing Letters

By feeding a dog with oil and with radioactive phosphorus (as sodium phosphate) and then determining the proportion of 'labelled' phosphorus in the lecithin of the blood and of the intestine, Prof. G. Hevesy and E. Lundgaard find that the additional lecithin found in the blood contains only a small amount of the active phosphorus, and conclude that during the absorption of neutral fats lecithin is formed outside the intestinal tract.

Drs. J. R. Edisbury, J. A. Lovern and R. A. Morton state that fish viscera other than liver contain vitamin A, and that halibut viscera constitute a very rich and hitherto neglected source of the vitamin. Evidence is adduced that vitamin A in liver is, at least in part, associated with protein.

From the intensity of the components of the hyperfine structure of the resonance line of potassium, Dr. D. Jackson and H. Kuhn deduce that the magnetic moment of K39 is positive, and that the nuclear spin has a value of $3/2$, in agreement with the findings of Millman, Fox and Rabi. The centre of gravity of the components of K41 overlaps the weaker component of K39.

An increase in the number of kicks in a 'neutron' counter when placed inside a lead chamber leads B. Arakatsu, K. Kimura and Y. Uemura to assume that neutrons are liberated from lead by cosmic ray photons. When the lead chamber is filled with paraffin, a further increase in the number of kicks of the counter is observed.

Investigations of oxide films on iron by means of electron diffraction throws further light on the three oxide layers (composed of ferrous, magnetic and ferric oxide). T. Iimori gives a diagram showing the regions of stability of the various forms of iron oxide and concludes that, with rising temperature, iron atoms migrate more vigorously towards the surface and check any further oxidation of the lower oxides.

N. S. Nagendra Nath states that the asymmetry in the curve showing the energy distribution of the electrons emitted by radioactive substances (β -decay) is explainable on the assumption that the final process consists of a shower of neutrinos, the number in the shower depending on the transition energy of the nucleus.

An inexpensive low-temperature thermostat, useful

also as a cold aquarium, is described by L. C. Beadle and F. A. Booth. A constant temperature is maintained by means of a controlled circulation of water from an ice tank, the flow being induced by a stream of air bubbles in a connecting tube.

Prof. C. S. Gibson directs attention to the production of thin gold films or mirrors on glass and other surfaces by deposition from organic gold compounds such as diethylmonobromogold.

Dr. S. C. Blacktin describes experiments indicating that, with a fine coal dust, its spontaneous electrical activity varies with the treatment to which the dust is submitted, and that such activity seems to increase with the increase of adsorbed material on the particles and to decrease with decrease of such adsorbed material.

D. A. Peak discusses the evidence concerning certain aspects of the structure of sterols and bile acids and suggests that the fusion of the *C* and *D* rings is in the *cis* and not in *trans* position as hitherto believed.

The separation of the *cis* form of azobenzene by extracting an acetone solution exposed to light with water and then further extracting the aqueous solution with chloroform is described by G. S. Hartley. The *cis* and *trans* forms come to equilibrium under usual conditions, the change being activated by light. The *cis* form has a greater absorption coefficient for blue light and its melting point is somewhat higher than that of normal azobenzene. In benzene solution it has a dipole moment of 3.0 Debye units.

By heating strongly stretched hydrated cellulose (viscose silk) for half an hour at $200^\circ C$. in water or in formamide, Prof. K. H. Meyer and N. P. Badenhuizen, jun., find that it is changed into native cellulose, as shown by X-ray diffraction patterns. The authors consider that at 200° – $300^\circ C$. native cellulose is the stable form and hydrate cellulose is the non-stable.

A small amount of a crystalline dinitro-phenyl hydrazine derivative which appears to be that of ascorbic acid has been separated from urine by Dr. C. P. Stewart, H. Scarborough and Dr. P. J. Drumm.

A diene synthesis which may help towards the synthesis of cholesterol and similar substances is described by A. B. Meggy and Prof. R. Robinson.

Research Items

'Woman Marriage' in Dahomey

THE institution of a form of marriage in which one woman takes another to wife has been recorded in Africa among peoples so far distant from one another as in northern and southern Nigeria, the Anglo-Egyptian Sudan and the Union of South Africa. It was observed by Dr. Melville J. Herakovits in Dahomey in 1931 (*Africa*, 10, 3). Dahomean marriages take thirteen different forms, falling into two general classes, in one of which, 'woman-with-money' are comprised all forms in which the marriage dues are paid by the spouse to the bride's father, while in the form 'friend-custody' no such payment is made. A woman may marry another woman, paying the dues and performing all the duties required in the first class; but nevertheless her marriage is spoken of as if it belonged to the second. In the first class of marriage the resultant offspring are under the control of the father; but in the second the mother retains control of her children. Woman marriage is rare among commoners, but frequent in upper-class families, particularly among royalty. It is based on the fact that women frequently become wealthy. They may then wish, especially if barren, to build up a compound of their own. To effect this a wife is married to whom the 'husband' admits a male friend or member of her household, the children who may result being regarded as her own, and competent to inherit the property of the house she has built up on this basis. The marriage does not necessarily imply homosexual relations. The motivating force, the desire for prestige and economic power, reflects the dominant Dahomean patterns of thought and the fundamental forces that underlie their behaviour. No stigma is attached to the parties contracting such marriages, and in fact the woman 'husband' is respected on account of her wealth and the number of persons she controls in her compound.

Prontosil in Puerperal Infections

IN the Section of Obstetrics and Gynaecology of the British Medical Association during its recent meeting in Belfast, Mr. G. F. Gibberd opened a discussion on the use of prontosil and similar compounds in the treatment of puerperal infections caused by haemolytic streptococci. After a preliminary reference to dosage, he compared a series of 167 cases of puerperal infection treated at Queen Charlotte's Hospital with a control series treated in this hospital during the last two years before the introduction of the new drug. The death-rate was much reduced, and the time spent in hospital was much shorter in prontosil-treated cases. Dr. Doris Brown reported on the use of prontosil in the Royal Maternity Hospital, Belfast. For the three years before the introduction of prontosil the death-rate for cases of septicaemia was 87.5 per cent, and the mortality for all cases due to infection by the haemolytic streptococcus was 23.5 per cent. Since the use of the drug the death-rate in cases of septicaemia was 28.57 per cent, and for all cases of puerperal infection 6.6 per cent. Prof. Chaasar Moir referred to the remarkable effect prontosil had in combating *B. coli* infections of the urinary tract.

Factors of Vocational Guidance

IN an article in the *Human Factor* (11, Nos. 7-8), Dr. Oesser discusses the problem of vocational guidance. He believes that while most people acknowledge its importance, few recognize its complexities. He analyses some of the psychological aspects affecting individual cases, and points out the interrelation between these and social and economic factors. He considers the problem for those who leave school at the age of fourteen years. Economic and social factors, he says, limit the individual's sphere of choice. The child of poor parents must earn an immediate living; an individual may have both the ability and the inclination to enter a certain trade, but may be forced by the condition of the labour market into another for which he has the ability but not the inclination; opportunities of employment vary in different neighbourhoods; the social status accompanying each occupation varies; the tradition of the family circle will give arbitrary value to certain kinds of work. The psychological factors fall into two parts: those that determine technical ability, and that depend on physical, temperamental and intellectual endowments; and those that determine personal choice and preference. Physical and intellectual endowments are measurable; but temperamental fitness is more difficult to assess, and together with the factors determining personal choice has its source in unconscious mental processes. Thus the data that are required for adequate vocational guidance range from the more general psycho-biological through social and economic to the deeply individual.

Sexual Periodicity

IN a paper (*Proc. Roy. Soc., B*, 123, 413; 1937) which is really a supplement to the Croonian Lecture given by him in 1936, Dr. F. H. A. Marshall summarizes evidence of the factors controlling the sexual seasons of various animals. Ruminants breed when the days are getting shorter, whether they live in the northern or the southern hemisphere. Individual ruminants which have been transported across the equator have been known to adapt themselves at once, and have two rutting seasons in one year. Ruminants on the equator usually have no sexual season. Most other mammals breed in the spring, and species transferred from the northern to the southern hemisphere conform to the seasonal conditions of the south. The same is generally true of birds. Rowan showed that, in some birds in any event, the lengthening of daylight was the important factor causing the onset of the sexual season. Similar experiments have been done with various other animals, and although it has frequently been found that light increases sexual activity, this is not always so.

Biology of Plankton Animals

MUCH information of interest is given on the biology of three important plankton organisms, *Calanus finmarchicus*, *Sagitta setosa* and *Sagitta elegans*, in the North Sea by R. S. Wimpenny (*Min. Agric. Fish., Fishery Invest., Ser. II*, 15, No. 3, 1936, pp. 1-53, 1937). The seasonal observations have been

based mainly on a line of stations between Flam-borough Head and the south-west patch of the Dogger Bank. Detailed observations were made on the breeding, growth and feeding of the three species, and have afforded a welcome extension to somewhat similar knowledge gained at Plymouth and Millport. All three species tended to be smaller than at Plymouth; this was thought to be connected with the shallow conditions of the southern North Sea, there being, for example, a decrease in size of *S. setosa* in the North Sea from north to south. The breeding periods of *Sagitta* also appeared to be fewer than at Plymouth. It appears that *S. setosa* is characteristic of mixed North Sea or 'Bank' waters, while the other two species occur in water of more oceanic origin. Additional information is given on the relation between zooplankton and phytoplankton, and the suggestion is put forward that phytoplankton concentrations may play the part of breeding and nursery grounds for zooplankton species.

Bacteriosis of Cherry Trees

THE serious damage caused by bacterial 'die-back' of sweet cherries in many English orchards is described in a recent paper by H. Wormald (*J. Pom. and Hort. Sci.*, 16, 1, 35; 1937). The symptoms consist of stem, crotch and branch cankers, shoot wilt, bud and spur blight, leaf spots and occasionally fruit spots. Certain varieties have proved to be commonly attacked, and some varieties seem to suffer less than others. Two organisms, *Pseudomonas prunicola* and *P. mors-prunorum*, have been isolated from a number of infected trees and are regarded as responsible for bacteriosis of sweet cherries in Great Britain. The latter, which also causes bacterial canker in plums, is more widespread. Control is difficult, but infection may be reduced by avoiding mechanical injury, such as pruning, in autumn, winter and early spring. Infected parts may be excised early in the year and the wounds covered with an antiseptic dressing. Mercury-glycerine or zinc chloride is suggested. Some control has been achieved by spraying with Bordeaux mixture in autumn, but several varieties suffer foliage damage with this treatment. There is no evidence that application of lime to the soil induces resistance to bacteriosis. Stocks as well as varieties vary in susceptibility, and it is possible that suitable resistant stocks may be found on which to graft susceptible varieties. Some interesting observations on the susceptibility of different varieties at East Malling are described (*ibid.*, p. 25) by N. H. Grubb, and certain questions of nomenclature and the effect of local conditions are discussed.

Crosses between Radish and Turnip

RECIPROCAL crosses were made between radish ($n = 9$) and turnip ($n = 10$) by Messrs. L. E. Morris and R. H. Richharia (*J. Genet.*, 34, No. 2). With turnip as female parent, 428 flowers yielded 23 seeds, 19 of which germinated. Their characters indicated that they were diploid hybrids. In the reciprocal cross, from particular parent plants 128 flowers yielded 5 seeds. Two of the resulting plants were like radishes (accidental selfs?), one was like the reciprocal hybrids and one was triploid, having $2n = 28$ chromosomes. It probably came from the fertilization of a diploid radish egg-cell. This triploid hybrid open-pollinated gave a varied progeny, including two hexaploids with $2n = 56$ which resembled the triploid but were almost sterile. The

functional eggs of the triploid plant were chiefly triploid, but some had 9 chromosomes and were genetically like the radish. The pollen of this plant also showed a range from 9 probably up to $3n$, but when used on radish the functioning grains had mostly 9 but some had 10 chromosomes. Triploid pollen grains apparently did not function on the radish stigma.

Roaring Sands of the Kalahari Desert

MR. A. D. LEWIS has recently given an interesting account of these sands (*S. African Geog. J.*, 19, 33-49; 1936). They lie at the south end of an elongated patch of whitish sand dunes near the south-east corner of the Kalahari desert, and the roars are heard most intensely along the southern face, which rises nearly 100 ft. at a slope of about 1 in 2. Compared with the rest of the desert sands, the grains are perhaps more rounded and of a more uniform size and shape. Mr. Lewis describes two types of noise, a roar caused by pushing the sands forward in a heaped-up manner and a hum by keeping the sand moving slowly down the slope. A very loud roar is produced by sitting on the slope and sliding down it in slow jerks. In the still of the early evening or morning, such a noise is easily heard, like the rumbling of distant thunder, at a distance of 600 yd. Merely moving the fingers up and down the sand produces a roar, the upward motion giving a higher note than the downward. Samples of the sand were taken in bags to Pretoria, and it was found that a roar was obtained by tilting the bag over sharply when half empty. If the bags were left open, the roar was lost after a few weeks, though it could be restored for a short time by heating the sand in an oven.

Mineral Position of the British Empire

A REMARKABLY comprehensive and instructive publication on the mineral industries of the British Empire has recently been issued under the above title, by the Mineral Resources Department of the Imperial Institute (pp. 166, price 4s.). Commencing with a comparison between world and Empire outputs of all the more important minerals used in 1929 and 1935, the work goes on to survey the many changes bearing on production that have occurred during this period. Graphical illustrations of the variations in annual outputs of twelve essential commodities are given. It appears that the Empire as a whole is largely dependent on foreign sources of supply for eight mineral products only—antimony, borates, molybdenum, petroleum, potash, pyrites, mercury and sulphur. Many interesting facts are brought to light by the authoritative statistical data presented. Thus, in 1935 the Empire produced 86.6 per cent of the world's nickel and 68.2 per cent of the world's asbestos, but both these percentages are considerably lower than in 1929. Also, in spite of a greatly increased output of gold, the Empire proportion fell from 72.7 per cent in 1929 to 58.3 per cent in 1935. There have also been decreases in the Empire percentages of chrome ore, manganese ore and diamonds. On the other hand, there have been decided increases in the Empire percentages of copper and lead ores. The total value of the Empire's mineral output during 1935 was about £400,000,000, of which the United Kingdom contributed nearly 42 per cent, South Africa a little more than 21 per cent and Canada 16 per cent. It is a striking fact that the value of the coal output of the United Kingdom represents about 37 per cent of the total value of the whole of the

Empire output of all minerals. All who are concerned with mineral industries or with Empire problems in relation to world affairs will find this volume indispensable.

Cyclone Series in the Caribbean Sea

At a meeting of the Royal Meteorological Society on May 26, a paper was read by E. Kidson entitled "The Cyclone Series in the Caribbean Sea, October 17-24, 1935". The author mentioned the view held by some who have attempted to apply frontal methods of analysis to tropical cyclones that air which has passed across the equator acts as the cold air. He referred to fronts found by K. R. Ramanathan and K. P. Ramakrishnan in Indian depressions of July and August, in which old monsoon air heated over India performed the role of the warm air-mass and fresh monsoon air the role of the cold air-mass; but stated that in the south-western Pacific the colder air of tropical cyclones undoubtedly came from higher southern latitudes and not from the far side of the equator. The paper is concerned with cyclonic developments encountered by the author on two occasions when he was crossing the Caribbean Sea after passing through the Panama Canal, and is illustrated by a series of synoptic charts with frontal analysis. In these he found more than one case where the warm air-mass clearly arrived from the south or south-west after having crossed the equator, in contradiction to the theory mentioned above, but in support of the observations in the south-west Pacific. It was noted, however, that air entering the Caribbean Sea from the south-west has first to cross the cold waters south of Panama and that such air will tend to be chilled in its lowest layers in consequence. This may easily lead to the warmth of the current as a whole being overlooked and thence to its being mistakenly regarded as the cold supply in any frontal development on account of its relatively low surface temperature.

Cyclol Theory of the Structure of Insulin

UNTIL recently the only comprehensive theory of protein structure was the polypeptide chain theory put forward by Emil Fischer. This is somewhat difficult to reconcile with the globular character of the soluble protein molecules first indicated by Svedberg's ultra-centrifuge measurements and later also supported by X-ray measurements on pepsin and insulin, and it is evidently of the greatest importance that other theoretically possible arrangements of amino-acids should be considered. One such has been examined in detail by Dr. D. M. Wrinn, who has shown that it might be possible to unite amino-acid residues through imino links in a laminar pattern—the cyclol structure. This laminar structure may then be folded into a restricted number of geometrically plausible space enclosing networks. For insulin, Dr. Wrinn proposes a cyclol structure built out of 288 residues united in a network of this kind which covers the surface of a truncated tetrahedron (*Science*, 85, 566; 1937). This polyhedral configuration would give the molecule the globular character required by Svedberg's data, and also the trigonal symmetry suggested by the X-ray evidence, provided that the actual amino-acid residues are symmetrically distributed over its surface. Along the trigonal axis the dimensions of the cyclol molecule would fit it fairly closely into the crystal unit cell, but at right angles to this there is very much more space, and it is suggested that this is filled by tyrosine residues held together by zinc or

other cations. Very much more experimental evidence is, of course, necessary before such a structure could be considered established, but in any event the construction of the models proposed is of great interest.

Projection Television

At a convention of the Institute of Radio Engineers held on May 10-12, several papers were presented dealing with recent developments in television. Two of these, by Dr. V. K. Zworykin, Mr. W. H. Painter and Dr. R. R. Law, described the development of a new electron tube by means of which an enlarged, projected image may be obtained of the picture normally seen on the fluorescent screen of a cathode ray tube. Some brief details, with an illustration of the device, are given in the June issue of *Electronics*. The tube illustrated contains an electron gun capable of delivering about 1.5 milliamperes at the cathode, of which about 0.4 milliamperes is actually delivered to the beam itself. The beam is accelerated by a potential of 10,000 volts on the last anode, and the resulting picture on the fluorescent screen itself, although only 2 in. $\times$ 1½ in. in size, is of exceptionally high brilliance. The tube is intended for use with a lens of $f/1.5$ aperture, and the standard size for the projected picture is 18 in. by 24 in., for which the illumination compares favourably with that of the ordinary 16 mm. home cinema picture. The screen material used in this tube is principally zinc orthosilicate of carefully controlled crystalline structure, which gives a brilliant yellow-green light and which is very stable under prolonged heavy bombardment. At the meeting referred to above, a demonstration of the operation of this projection tube was given by the engineers of the Radio Corporation of America. A video signal was obtained from a still picture using 30 frames a second and 343 lines without interlacing. A special screen, about three by four feet in size, was employed, and the picture obtained was of high brilliance and quality. As an additional demonstration, the small screen was removed and the image projected on to the standard screen used for lantern slides. In this case, the picture was 8 ft. $\times$ 11 ft. in size and was stated to be readily visible to all those present in the room, which was about fifty feet long.

Masses and Parallaxes of Binary Stars

DR. O. BARNES has published a paper on the statistical determination of masses and parallaxes of binary stars (*Mon. Not. Roy. Astro. Soc.*, 97, 6; April 1937), in which he submits the mean values of $\rho\omega^3$ and $(\rho\omega^3)^{1/2}$ for orbits of given eccentricity, these quantities appearing in the equations used for determining the combined mass and the parallax respectively. In addition, he gives the mean values for $(\rho\omega^3)^{1/3}$ and $(\rho\omega^3)^{1/4}$ which are required for the estimation of the probable errors. From 124 orbits as computed by Prof. R. K. Young, it is found that with the mean value of e between 0 and 1, $\bar{\epsilon}^2 = 0.322$ and $\bar{\epsilon}^4 = 0.14$; from which $\rho\omega^3 = 16.9(a^3/P^3)$ and also $(\rho\omega^3)^{1/2} = 2.38(a^3/P^3)^{1/2}$. In the first case, the probable error in a single determination is 49 per cent, and in the second case it is 21 per cent. If a somewhat different mean value of e be taken, the numerical results are essentially unchanged. For example, if $\bar{\epsilon}^2 = 0.263$, $\bar{\epsilon}^4 = 0.11$, the coefficients given in the above equations become 17.3 and 2.42 respectively, very small changes for a considerable change in e .

Royal Society of Canada

ANNUAL MEETING AT TORONTO

THE annual meeting of the Royal Society of Canada was held at the University of Toronto on May 25-28, under the presidency of Mr. Lawrence J. Burpee of Ottawa, who took as the subject of his presidential address "The Discovery of Canada". The Flavelle Medal for 1937 was awarded to Dr. F. D. Adams, the Lorne Pierce Medal to Prof. Stephen Leacock, and the Tyrrell Medal to Mr. Aegidius Fauteux. Prof. A. G. Huntman, consulting director of the Biological Board of Canada and editor of its publications, and professor of marine biology in the University of Toronto, was elected president for the year 1937-38.

In Section 1 (French, Literature, History, etc.) fifteen papers were read, and in Section 2 (English Literature, History, etc.) twenty-one papers.

In Section 3 (Chemical, Mathematical and Physical Sciences) 142 papers were presented, 47 by title only. One third were presented to the whole Section, the remainder to four subsections (Astronomy, Chemistry, Mathematics, Physics). Three new fellows were elected to the Section: Prof. A. R. Gordon, of the University of Toronto; R. L. Jeffery, of Acadia University, and W. H. Watson, of McGill University.

The feature of the meetings of Section 3 was its presidential address by John Patterson, director of the Meteorological Service of Canada, in which he outlined recent advances made in this service. The necessity of a continuous forecasting service for the recent expansion in aviation has given a new impetus to research, has led to increase in the number of observation centres, and has increased the personnel. The address was followed by a symposium by A. Thomson and various members of the meteorological staff, in which the results of temperature, water vapour content, and pressure distribution in the upper atmosphere at various Canadian stations were given. Observations at the National Research Laboratory, communicated by D. C. Rose, showed that the advance of polar front is the cause of variations in potential gradient.
